

Leandro Vendramin

# Associative algebras

Notes

Thursday 23<sup>rd</sup> November, 2023

# Preface

The notes correspond to the master course *Associative Algebra* of the Vrije Universiteit Brussel, Faculty of Sciences, Department of Mathematics and Data Sciences. The course is divided into twelve two-hour lectures.

The content presented here draws heavily from [2], [8], and [18]. Additionally, I have followed the outstanding blog on abstract algebra by Yaghoub Sharif.

Prerequisites: An undergraduate “abstract algebra” course. See for example my notes on Rings and modules.

This version was compiled on Thursday 23<sup>rd</sup> November, 2023 at 12:06. Please send comments and corrections to me at `Leandro.Vendramin@vub.be`. Thanks go to Luca Descheemaeker, Lukas Simons.

# Lecture 1

## §1. Semisimple algebras

We will devote two lectures to the study of finite-dimensional semisimple algebras. The main goal is to prove Artin–Wedderburn theorem.

**Definition 1.1.** An **algebra** (over the field  $K$ ) is a vector space (over  $K$ ) with an associative multiplication  $A \times A \rightarrow A$  such that  $a(\lambda b + \mu c) = \lambda(ab) + \mu(ac)$  and  $(\lambda a + \mu b)c = \lambda(ac) + \mu(bc)$  for all  $a, b, c \in A$ , and that contains an element  $1_A \in A$  such that  $1_A a = a 1_A = a$  for all  $a \in A$ .

Note that a ring  $A$  is an algebra over  $K$  if and only if there is a ring homomorphism  $K \rightarrow Z(A)$ , where  $Z(A) = \{a \in A : ab = ba \text{ for all } b \in A\}$  is the center of  $A$ , such that  $1_K \rightarrow 1_A$ .

**Definition 1.2.** An algebra  $A$  is **commutative** if  $ab = ba$  for all  $a, b \in A$ .

The **dimension** of an algebra  $A$  is the dimension of  $A$  as a vector space. This is why we want to consider algebras, as they are a linear version of rings. Often, our arguments will use the dimension of the underlying vector space.

**Example 1.3.** The field  $\mathbb{R}$  is a real algebra and  $\mathbb{C}$  is a complex algebra. Moreover,  $\mathbb{C}$  is a real algebra.

Any field  $K$  is an algebra over  $K$ .

**Example 1.4.** If  $K$  is a field, then  $K[X]$  is an algebra over  $K$ .

Similarly, the polynomial ring  $K[X, Y]$  and the ring  $K[[X]]$  of power series are examples of algebra over  $K$ .

**Example 1.5.** If  $A$  is an algebra, then  $M_n(A)$  is an algebra.

**Example 1.6.** The set of continuous maps  $[0, 1] \rightarrow \mathbb{R}$  is a real algebra with the usual point-wise operations  $(f + g)(x) = f(x) + g(x)$  and  $(fg)(x) = f(x)g(x)$ .

**Example 1.7.** Let  $n \in \mathbb{Z}_{>0}$ . Then  $K[X]/(X^n)$  is a finite-dimensional algebra. It is the **truncated polynomial algebra**.

**Example 1.8.** Let  $G$  be a finite group. The vector space  $\mathbb{C}[G]$  with basis  $\{g : g \in G\}$  is an algebra with multiplication

$$\left( \sum_{g \in G} \lambda_g g \right) \left( \sum_{h \in G} \mu_h h \right) = \sum_{g, h \in G} \lambda_g \mu_h (gh).$$

Note that  $\dim \mathbb{C}[G] = |G|$  and  $\mathbb{C}[G]$  is commutative if and only if  $G$  is abelian. This is the **complex group algebra** of  $G$ .

If  $G$  is an infinite group, the complex group algebra  $\mathbb{C}[G]$  is defined as the set of finite linear combinations of elements of  $G$  with the usual operations.

**Definition 1.9.** Let  $K$  be a field and  $A$  and  $B$  be  $K$ -algebras. An algebra **homomorphism** is a ring homomorphism  $f: A \rightarrow B$  that is also a  $K$ -linear map.

The complex conjugation map  $\mathbb{C} \rightarrow \mathbb{C}, z \mapsto \bar{z}$ , is a ring homomorphism that is not an algebra homomorphism over  $\mathbb{C}$ .

**Exercise 1.10.** Let  $G$  be a non-trivial finite group. Then  $\mathbb{C}[G]$  has zero divisors.

If  $A$  is an algebra, then  $\mathcal{U}(A)$  is the set of units of  $A$ .

**Exercise 1.11.** Let  $A$  be a  $K$ -algebra and  $G$  be a finite group. If  $f: G \rightarrow \mathcal{U}(A)$  is a group homomorphism, then there exists an algebra homomorphism  $\varphi: K[G] \rightarrow A$  such that  $\varphi|_G = f$ .

**Definition 1.12.** An **ideal** of an algebra is an ideal of the underlying ring.

Similarly, one defines left and right ideals of an algebra.

If  $A$  is an algebra, then every left ideal of the ring  $A$  is a vector space. Indeed, if  $I$  is a left ideal of  $A$  and  $\lambda \in K$  and  $x \in I$ , then

$$\lambda x = \lambda(1_A x) = (\lambda 1_A)x.$$

Since  $\lambda 1_A \in A$ , it follows that  $\lambda I = (\lambda 1_A)I \subseteq I$ . Similarly, every right ideal of the ring  $A$  is a vector space.

If  $A$  is an algebra and  $I$  is an ideal of  $A$ , then the quotient ring  $A/I$  has a unique algebra structure such that the canonical map  $A \rightarrow A/I, a \mapsto a + I$ , is a surjective algebra homomorphism with kernel  $I$ .

**Definition 1.13.** Let  $A$  be an algebra over the field  $K$ . An element  $a \in A$  is **algebraic** over  $K$  if there exists a non-zero polynomial  $f \in K[X]$  such that  $f(a) = 0$ .

If every element of  $A$  is algebraic, then  $A$  is said to be algebraic

In the algebra  $\mathbb{R}$  over  $\mathbb{Q}$ , the element  $\sqrt{2}$  is algebraic, as  $\sqrt{2}$  is a root of the polynomial  $X^2 - 2 \in \mathbb{Q}[X]$ . A famous theorem of Lindemann proves that  $\pi$  is not algebraic over  $\mathbb{Q}$ . Every element of the real algebra  $\mathbb{R}$  is algebraic.

**Proposition 1.14.** *Every finite-dimensional algebra is algebraic.*

*Proof.* Let  $A$  be an algebra with  $\dim A = n$  and let  $a \in A$ . Since  $\{1, a, a^2, \dots, a^n\}$  has  $n+1$  elements, it is a linearly dependent set. Thus there exists a non-zero polynomial  $f \in K[X]$  such that  $f(a) = 0$ .  $\square$

**Definition 1.15.** A **module** over an algebra  $A$  is a module over the ring  $A$ .

Similarly, one defines **submodules** of  $A$ -modules.

**Definition 1.16.** Let  $A$  be a  $K$ -algebra. A **homomorphism** of  $A$ -modules  $f: M \rightarrow N$  is a  $K$ -linear map such that  $f(a \cdot m) = a \cdot f(m)$  for all  $a \in A$  and  $m \in M$ .

It is a straightforward exercise to prove the isomorphism theorems.

Let  $A$  be a finite-dimensional  $K$ -algebra. If  $M$  is a module over the ring  $A$ , then  $M$  is a vector space with

$$\lambda m = (\lambda 1_A) \cdot m,$$

where  $\lambda \in K$  and  $m \in M$ . Moreover,  $M$  is finitely generated if and only if  $M$  is finite-dimensional.

**Example 1.17.** If  $M$  is a module over a finite-dimensional  $K$ -algebra  $A$ , one defines  $\text{End}_A(M)$  as the set of module homomorphisms  $M \rightarrow M$ . The set  $\text{End}_A(M)$  is indeed a  $K$ -algebra with

$$(f+g)(m) = f(m) + g(m), \quad (\lambda f)(m) = \lambda f(m) \quad \text{and} \quad (fg)(m) = f(g(m))$$

for all  $f, g \in \text{End}_A(M)$ ,  $\lambda \in K$  and  $m \in M$ .

**Example 1.18.** An algebra  $A$  is a module over  $A$  with left multiplication, that is  $a \cdot b = ab$ ,  $a, b \in A$ . This module is the (left) **regular representation** of  $A$  and it will be denoted by  ${}_A A$ .

**Definition 1.19.** Let  $A$  be an algebra and  $M$  be a module over  $A$ . Then  $M$  is **simple** if  $M \neq \{0\}$  and  $\{0\}$  and  $M$  are the only submodules of  $M$ .

**Definition 1.20.** Let  $A$  be a finite-dimensional algebra and  $M$  be a finite-dimensional module over  $A$ . Then  $M$  is **semisimple** if  $M$  is a direct sum of finitely many simple submodules.

By definition, the zero module is semisimple. Moreover, any finite direct sum of semisimples is semisimple.

**Lemma 1.21 (Schur).** *Let  $A$  be an algebra. If  $S$  and  $T$  are simple modules and  $f: S \rightarrow T$  is a non-zero module homomorphism, then  $f$  is an isomorphism.*

*Proof.* Since  $f \neq 0$ ,  $\ker f$  is a proper submodule of  $S$ . Since  $S$  is simple, it follows that  $\ker f = \{0\}$ . Similarly,  $f(S)$  is a non-zero submodule of  $T$  and hence  $f(S) = T$ , as  $T$  is simple.  $\square$

**Proposition 1.22.** *If  $A$  is a finite-dimensional algebra and  $S$  is a simple module, then  $S$  is finite-dimensional.*

*Proof.* Let  $s \in S \setminus \{0\}$ . Since  $S$  is simple,  $\varphi: A \rightarrow S, a \mapsto a \cdot s$ , is a surjective module homomorphism. In particular, by the first isomorphism theorem,  $A/\ker \varphi \simeq S$  and hence  $\dim S = \dim(A/\ker \varphi) \leq \dim A$ .  $\square$

**Proposition 1.23.** *Let  $M$  be a finite-dimensional module. The following statements are equivalent.*

- 1)  $M$  is semisimple.
- 2)  $M = \sum_{i=1}^k S_i$ , where each  $S_i$  is a simple submodule of  $M$ .
- 3) If  $S$  is a submodule of  $M$ , then there is a submodule  $T$  of  $M$  such that  $M = S \oplus T$ .

*Proof.* We first prove that 2)  $\implies$  3). Let  $N \neq \{0\}$  be a submodule of  $M$ . Since  $N \neq \{0\}$  and  $\dim M < \infty$ , there exists a submodule  $T$  of  $M$  of maximal dimension such that  $N \cap T = \{0\}$ . If  $S_i \subseteq N \oplus T$  for all  $i \in \{1, \dots, k\}$ , then, as  $M$  is the sum of the  $S_i$ , it follows that  $M = N \oplus T$ . If, however, there exists  $i \in \{1, \dots, k\}$  such that  $S_i \not\subseteq N \oplus T$ , then  $S_i \cap (N \oplus T) \subseteq S_i$ . Since the module  $S_i$  is simple, it follows that  $S_i \cap (N \oplus T) = \{0\}$ . Thus  $N \cap (S_i \oplus T) = \{0\}$ , a contradiction to the maximality of  $\dim T$ .

The implication 1)  $\implies$  2) is trivial.

Finally, we prove that 3)  $\implies$  1). We proceed by induction on  $\dim M$ . The result is clear if  $\dim M = 1$ . Assume that  $\dim M \geq 2$  and let  $S$  be a non-zero submodule of  $M$  of minimal dimension. In particular,  $S$  is simple. By assumption, there exists a submodule  $T$  of  $M$  such that  $M = S \oplus T$ . We claim that  $T$  satisfies the assumptions. If  $X$  is a submodule of  $T$ , then, since  $T$  is also a submodule of  $M$ , there exists a submodule  $Y$  of  $M$  such that  $M = X \oplus Y$ . Thus

$$T = T \cap M = T \cap (X \oplus Y) = X \oplus (T \cap Y),$$

as  $X \subseteq T$ . Since  $\dim T < \dim M$  and  $T \cap Y$  is a submodule of  $T$ , the inductive hypothesis implies that  $T$  is a direct sum of simple submodules. Hence  $M$  is a direct sum of simple submodules.  $\square$

**Proposition 1.24.** *If  $M$  is a semisimple module and  $N$  is a submodule, then  $N$  and  $M/N$  are semisimple.*

*Proof.* Assume that  $M = S_1 + \dots + S_k$ , where each  $S_i$  is a simple submodule. If  $\pi: M \rightarrow M/N$  is the canonical map, the techniques used in Schur's lemma imply that each restriction  $\pi|_{S_i}$  is either zero or an isomorphism with the image. Since

$$M/N = \pi(M) = \sum_{i=1}^k (\pi|_{S_i})(S_i),$$

it follows that  $M/N$  is a direct sum of finitely many simples.

§1 Semisimple algebras

We now prove that  $N$  is semisimple. By assumption, there exists a submodule  $T$  such that  $M = N \oplus T$ . The quotient  $M/T$  is semisimple by the previous paragraph, so it follows that

$$N \simeq N/\{0\} = N/(N \cap T) \simeq (N \oplus T)/T = M/T$$

is also semisimple.  $\square$

**Definition 1.25.** An algebra  $A$  is **semisimple** if every finitely generated  $A$ -module is semisimple.

**Proposition 1.26.** *Let  $A$  be a finite-dimensional algebra. Then  $A$  is semisimple if and only if the regular representation of  $A$  is semisimple.*

*Proof.* Let us prove the non-trivial implication. Let  $M$  be a finitely generated module, say  $M = (m_1, \dots, m_k)$ . The map

$$\bigoplus_{i=1}^k A \rightarrow M, \quad (a_1, \dots, a_k) \mapsto \sum_{i=1}^k a_i \cdot m_i,$$

is a surjective homomorphism of modules, where  $A$  is considered as a module with the regular representation. Since  $A$  is semisimple, it follows that  $\bigoplus_{i=1}^k A$  is semisimple. Thus  $M$  is semisimple, as it is isomorphic to the quotient of a semisimple module.  $\square$

**Theorem 1.27.** *Let  $A$  be a finite-dimensional semisimple algebra. Assume that the regular representation can be decomposed as  ${}_A A = \bigoplus_{i=1}^k S_i$  where each  $S_i$  is a simple submodule. If  $S$  is a simple module, then  $S \simeq S_i$  for some  $i \in \{1, \dots, k\}$ .*

*Proof.* Let  $s \in S \setminus \{0\}$ . The map  $\varphi: A \rightarrow S, a \mapsto a \cdot s$ , is a surjective module homomorphism. Since  $\varphi \neq 0$ , there exists  $i \in \{1, \dots, k\}$  such that some restriction  $\varphi|_{S_i}: S_i \rightarrow S$  is non-zero. By Schur's lemma, it follows that  $\varphi|_{S_i}$  is an isomorphism.  $\square$

As a corollary, a finite-dimensional semisimple algebra admits only finitely many isomorphism classes of simple modules. When we say that the  $S_1, \dots, S_k$  are the simple modules of an algebra, this means that the  $S_i$  are the representatives of isomorphism classes of all simple modules of the algebra, that is that each simple module is isomorphic to some  $S_i$  and, moreover,  $S_i \neq S_j$  whenever  $i \neq j$ .

## Lecture 2

**Exercise 1.28.** If  $A$  and  $B$  are algebras,  $M$  is a module over  $A$  and  $N$  is a module over  $B$ , then  $M \oplus N$  is a module over  $A \times B$  with

$$(a, b) \cdot (m, n) = (a \cdot m, b \cdot n).$$

A **division algebra**  $D$  is an algebra such that every non-zero element is invertible, that is for all  $x \in D \setminus \{0\}$  there exists  $y \in D$  such that  $xy = yx = 1$ . Modules over division algebras are very much like vector spaces. For example, every finitely generated module  $M$  over a division algebra has a basis. Moreover, every linearly independent subset of  $M$  can be extended into a basis of  $M$ .

**Proposition 1.29.** *Let  $D$  be a division algebra, and  $V$  be a finite-dimensional module over  $D$ . Then  $V$  is a simple module over  $\text{End}_D(V)$  and there exists  $n \in \mathbb{Z}_{>0}$  such that  $\text{End}_D(V) \simeq nV$  is semisimple.*

*Sketch of the proof.* Let  $\{v_1, \dots, v_n\}$  be a basis of  $V$ . A direct calculation shows that the map

$$\text{End}_D(V) \rightarrow \bigoplus_{i=1}^n V = nV, \quad f \mapsto (f(v_1), \dots, f(v_n)),$$

is an injective homomorphism of  $\text{End}_D(V)$ -modules. Since

$$\dim_D \text{End}_D(V) = n^2 = \dim_D(nV),$$

it follows that the map is an isomorphism. Thus

$$\text{End}_D(V) \simeq \bigoplus_{i=1}^n V.$$

It remains to show that  $V$  is simple. It is enough to prove that  $V = \text{End}_D(V) \cdot v = (v)$  for all  $v \in V \setminus \{0\}$ . Let  $v \in V \setminus \{0\}$ . If  $w \in V$ , then there exists  $f \in \text{End}_D(V)$  such that  $f \cdot v = f(v) = w$ . Thus  $w \in (v)$  and therefore  $V = (v)$ .  $\square$

The proposition states that if  $D$  is a division algebra, then  $D^n$  is a simple  $M_n(D)$ -module and that  $M_n(D) \simeq nD^n$  as  $M_n(D)$ -modules.

**Exercise 1.30.** Let  $M$ ,  $N$ , and  $X$  be modules. Prove that

$$\text{Hom}_A(M \oplus N, X) \simeq \text{Hom}_A(M, X) \times \text{Hom}_A(N, X). \quad (2.1)$$

**Theorem 1.31.** Let  $A$  be a finite-dimensional algebra and let  $S_1, \dots, S_k$  be the simple modules over  $A$ . If

$$M \simeq n_1 S_1 \oplus \dots \oplus n_k S_k,$$

then each  $n_j$  is uniquely determined.

*Proof.* Since each  $S_j$  is simple and  $S_i \neq S_j$  if  $i \neq j$ , Schur's lemma implies that  $\text{Hom}_A(S_i, S_j) = \{0\}$  whenever  $i \neq j$ . For each  $j \in \{1, \dots, k\}$ , routine calculations show that

$$\text{Hom}_A(M, S_j) \simeq \text{Hom}_A\left(\bigoplus_{i=1}^k n_i S_i, S_j\right) \simeq n_j \text{Hom}_A(S_j, S_j).$$

Since  $M$  and  $S_j$  are finite-dimensional vector spaces, it follows that  $\text{Hom}_A(M, S_j)$  and  $\text{Hom}_A(S_j, S_j)$  are both finite-dimensional vector spaces. Moreover, the identity  $\text{id}: S_j \rightarrow S_j$  is a module homomorphism and hence  $\dim \text{Hom}_A(S_j, S_j) \geq 1$ . Thus each  $n_j$  is uniquely determined, as

$$n_j = \frac{\dim \text{Hom}_A(M, S_j)}{\dim \text{Hom}_A(S_j, S_j)}. \quad \square$$

If  $A$  is an algebra, the **opposite algebra**  $A^{\text{op}}$  is the vector space  $A$  with multiplication  $A \times A \rightarrow A$ ,  $(a, b) \mapsto ba = a \cdot_{\text{op}} b$ . Clearly,  $A$  is commutative if and only if  $A = A^{\text{op}}$ .

**Lemma 1.32.** If  $A$  is an algebra, then  $A^{\text{op}} \simeq \text{End}_A(A)$  as algebras.

*Proof.* Note that  $\text{End}_A(A) = \{\rho_a : a \in A\}$ , where  $\rho_a : A \rightarrow A$ ,  $x \mapsto xa$ . Indeed, if  $f \in \text{End}_A(A)$ , then  $f(1) = a \in A$ . Moreover,  $f(b) = f(b1) = bf(1) = ba$  and hence  $f = \rho_a$ . The map  $A^{\text{op}} \rightarrow \text{End}_A(A)$ ,  $a \mapsto \rho_a$ , is bijective and it is an algebra homomorphism, as

$$\rho_a \rho_b(x) = \rho_a(\rho_b(x)) = \rho_a(xb) = x(ba) = \rho_{ba}(x). \quad \square$$

**Lemma 1.33.** If  $A$  is an algebra and  $n \in \mathbb{Z}_{>0}$ , then  $M_n(A)^{\text{op}} \simeq M_n(A^{\text{op}})$  as algebras.

*Proof.* Let  $\psi : M_n(A)^{\text{op}} \rightarrow M_n(A^{\text{op}})$ ,  $X \mapsto X^T$ , where  $X^T$  is the transpose matrix of  $X$ . Since  $\psi$  is a bijective linear map, it is enough to see that  $\psi$  is a homomorphism. If  $i, j \in \{1, \dots, n\}$ ,  $a = (a_{ij})$  and  $b = (b_{ij})$ , then

$$\begin{aligned}
(\psi(a)\psi(b))_{ij} &= \sum_{k=1}^n \psi(a)_{ik} \psi(b)_{kj} = \sum_{k=1}^n a_{ki} \cdot_{\text{op}} b_{jk} \\
&= \sum_{k=1}^n b_{jk} a_{ki} = (ba)_{ji} = ((ba)^T)_{ij} = \psi(a \cdot_{\text{op}} b)_{ij}. \quad \square
\end{aligned}$$

**Lemma 1.34.** *If  $S$  is a simple module and  $n \in \mathbb{Z}_{>0}$ , then*

$$\text{End}_A(nS) \simeq M_n(\text{End}_A(S))$$

*as algebras.*

*Sketch of the proof.* Let  $(\varphi_{ij})$  be a matrix with entries in  $\text{End}_A(S)$ . We define a map  $nS \rightarrow nS$  as follows:

$$\begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \mapsto \begin{pmatrix} \varphi_{11} & \cdots & \varphi_{1n} \\ \vdots & \ddots & \vdots \\ \varphi_{n1} & \cdots & \varphi_{nn} \end{pmatrix} \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} \varphi_{11}(x_1) + \cdots + \varphi_{1n}(x_n) \\ \vdots \\ \varphi_{n1}(x_1) + \cdots + \varphi_{nn}(x_n) \end{pmatrix}.$$

The reader should prove that the map

$$M_n(\text{End}_A(S)) \rightarrow \text{End}_A(nS)$$

is an injective algebra homomorphism. It is surjective. Indeed, if  $\psi \in \text{End}_A(nS)$  and  $i, j \in \{1, \dots, n\}$  one defines  $\psi_{ij}$  by

$$\psi \begin{pmatrix} x \\ 0 \\ \vdots \\ 0 \end{pmatrix} = \begin{pmatrix} \psi_{11}(x) \\ \psi_{21}(x) \\ \vdots \\ \psi_{n1}(x) \end{pmatrix}, \dots, \psi \begin{pmatrix} 0 \\ 0 \\ \vdots \\ x \end{pmatrix} = \begin{pmatrix} \psi_{1n}(x) \\ \psi_{2n}(x) \\ \vdots \\ \psi_{nn}(x) \end{pmatrix}. \quad \square$$

**Exercise 1.35.** Prove Lemma 1.34.

**Exercise 1.36.** Let  $M$ ,  $N$ , and  $X$  be modules. Prove that

$$\text{Hom}_A(X, M \oplus N) \simeq \text{Hom}_A(X, M) \times \text{Hom}_A(X, N). \quad (2.2)$$

**Theorem 1.37 (Artin–Wedderburn).** *Let  $A$  be a finite-dimensional semisimple algebra with  $k$  isomorphism classes of simple modules. Then*

$$A \simeq M_{n_1}(D_1) \times \cdots \times M_{n_k}(D_k)$$

*for some  $n_1, \dots, n_k \in \mathbb{Z}_{>0}$  and some division algebras  $D_1, \dots, D_k$ .*

*Proof.* Decompose the regular representation as a sum of simple modules and gather the simples by isomorphism classes to get

$$A = \bigoplus_{i=1}^k n_i S_i,$$

where each  $S_i$  is simple and  $S_i \neq S_j$  whenever  $i \neq j$ . Schur's lemma implies that

$$\text{End}_A(A) \simeq \text{End}_A\left(\bigoplus_{i=1}^k n_i S_i\right) \simeq \prod_{i=1}^k \text{End}_A(n_i S_i) \simeq \prod_{i=1}^k M_{n_i}(\text{End}_A(S_i)),$$

where each  $D_i = \text{End}_A(S_i)$  is a division algebra by Schur's lemma. Thus

$$\text{End}_A(A) \simeq \prod_{i=1}^k M_{n_i}(D_i).$$

Since  $\text{End}_A(A) \simeq A^{\text{op}}$ , it follows that

$$A = (A^{\text{op}})^{\text{op}} \simeq \prod_{i=1}^k M_{n_i}(D_i)^{\text{op}} \simeq \prod_{i=1}^k M_{n_i}(D_i^{\text{op}}).$$

Since each  $D_i$  is a division algebra, each  $D_i^{\text{op}}$  is also a division algebra.  $\square$

**Corollary 1.38 (Molien).** *If  $A$  is a finite-dimensional complex semisimple algebra with  $k$  isomorphism classes of simple modules, then*

$$A \simeq \prod_{i=1}^k M_{n_i}(\mathbb{C})$$

for some  $n_1, \dots, n_k \in \mathbb{Z}_{>0}$ .

*Proof.* By Wedderburn's theorem,

$$A \simeq \prod_{i=1}^k M_{n_i}(\text{End}_A(S_i)^{\text{op}}),$$

where  $S_1, \dots, S_k$  are representatives of the isomorphism classes of simple modules and each  $\text{End}_A(S_i)$  is a division algebra. We claim that

$$\text{End}_A(S_i) = \{\lambda \text{ id} : \lambda \in \mathbb{C}\} \simeq \mathbb{C}$$

for all  $i \in \{1, \dots, k\}$ . If  $f \in \text{End}_A(S_i)$ , then  $f$  has an eigenvalue  $\lambda \in \mathbb{C}$ . Since  $f - \lambda \text{ id}$  is not an isomorphism, Schur's lemma implies that  $f - \lambda \text{ id} = 0$ , that is  $f = \lambda \text{ id}$ . Thus  $\text{End}_A(S_i) \rightarrow \mathbb{C}, f \mapsto \lambda$ , is an algebra isomorphism. In particular,

$$A \simeq \prod_{i=1}^k M_{n_i}(\mathbb{C}). \quad \square$$

## §2. Group algebras

Let  $K$  be a field, and  $G$  be a group. The **group algebra**  $K[G]$  is the vector space (over  $K$ ) with basis  $\{g : g \in G\}$  and the algebra structure is given by the multiplication

$$\left( \sum_{g \in G} \lambda_g g \right) \left( \sum_{h \in G} \mu_h h \right) = \sum_{g, h \in G} \lambda_g \mu_h (gh).$$

Every element of  $K[G]$  is a finite sum of the form  $\sum_{g \in G} \lambda_g g$ .

**Exercise 2.1.** If  $G$  is non-trivial, then  $K[G]$  is not simple.

**Exercise 2.2.** Let  $G = C_n$  be the (multiplicative) cyclic group of order  $n$ . Prove that  $K[G] \simeq K[X]/(X^n - 1)$ .

**Exercise 2.3.** Let  $G$  be a finitely-generated torsion-free abelian group. Prove that  $K[G]$  is a domain.

**Exercise 2.4.** Let  $G$  be a group and  $\alpha = \sum_{g \in G} \lambda_g g \in K[G]$ . The **support** of  $\alpha$  is the set

$$\text{supp } \alpha = \{g \in G : \lambda_g \neq 0\}.$$

Prove that if  $g \in G$ , then  $\text{supp}(g\alpha) = g(\text{supp } \alpha)$  and  $\text{supp}(\alpha g) = (\text{supp } \alpha)g$ .

**Exercise 2.5.** Let  $G$  be a group and  $H$  be a subgroup of  $G$ . Let  $\alpha \in K[H]$ . Prove that  $\alpha$  is invertible (resp. a left zero divisor) in  $K[H]$  if and only if  $\alpha$  is invertible (resp. a left zero divisor) in  $K[G]$ .

**Exercise 2.6.** Let  $G = C_2 = \langle g \rangle \simeq \mathbb{Z}/2$  the (multiplicative) group with two elements. Note that every element of  $K[G]$  is of the form  $a + bg$  for some  $a, b \in K$ . Prove the following statements:

1) If the characteristic of  $K$  is different from two, then

$$K[G] \rightarrow K \times K, \quad a1 + bg \mapsto (a + b, a - b),$$

is an algebra isomorphism.

2) If the characteristic of  $K$  is two, then

$$K[G] \rightarrow \begin{pmatrix} K & K \\ 0 & K \end{pmatrix}, \quad a1 + bg \mapsto \begin{pmatrix} a + b & b \\ 0 & a + b \end{pmatrix},$$

is an algebra isomorphism.

If  $A$  is an algebra over  $K$  and  $\rho : G \rightarrow \mathcal{U}(A)$  is a group homomorphism, where  $\mathcal{U}(A)$  is the group of units of  $A$ , then the map

$$K[G] \rightarrow A, \quad \sum_{g \in G} \lambda_g g \mapsto \sum_{g \in G} \lambda_g \rho(g),$$

is an algebra homomorphism.

**Exercise 2.7.** Let  $G = C_3$  be the (multiplicative) group of three elements. Prove that  $\mathbb{R}[G] \simeq \mathbb{R} \times \mathbb{C}$ .

**Exercise 2.8.** Let  $G = \langle r, s : r^3 = s^2 = 1, sr s = r^{-1} \rangle$  be the dihedral group of six elements. Prove the following statements:

- 1)  $\mathbb{C}[G] \simeq \mathbb{C} \times \mathbb{C} \times M_2(\mathbb{C})$ .
- 2)  $\mathbb{Q}[G] \simeq \mathbb{Q} \times \mathbb{Q} \times M_2(\mathbb{Q})$ .

Maschke's theorem states that, if  $G$  is a finite group, then the group algebra  $\mathbb{C}[G]$  is semisimple. By Mollien's theorem,

$$\mathbb{C}[G] \simeq \prod_{i=1}^k M_{n_i}(\mathbb{C}),$$

where  $k$  is the number of (isomorphism classes of) simple  $\mathbb{C}[G]$ -modules. Moreover,

$$|G| = \dim \mathbb{C}[G] = \sum_{i=1}^k n_i^2.$$

**Theorem 2.9.** Let  $G$  be a finite group. The number of simple modules of  $\mathbb{C}[G]$  coincides with the number of conjugacy classes of  $G$ .

*Proof.* By Mollien's theorem,  $\mathbb{C}[G] \simeq \prod_{i=1}^k M_{n_i}(\mathbb{C})$ . Thus

$$Z(\mathbb{C}[G]) \simeq \prod_{i=1}^k Z(M_{n_i}(\mathbb{C})) \simeq \mathbb{C}^k.$$

In particular,  $\dim Z(\mathbb{C}[G]) = k$ . If  $\alpha = \sum_{g \in G} \lambda_g g \in Z(\mathbb{C}[G])$ , then  $h^{-1} \alpha h = \alpha$  for all  $h \in G$ . Thus

$$\sum_{g \in G} \lambda_{hgh^{-1}} g = \sum_{g \in G} \lambda_g h^{-1} g h = \sum_{g \in G} \lambda_g g$$

and hence  $\lambda_g = \lambda_{hgh^{-1}}$  for all  $g, h \in G$ . A basis for  $Z(\mathbb{C}[G])$  is given by elements of the form

$$\sum_{g \in K} g,$$

where  $K$  is a conjugacy class of  $G$ . Therefore  $\dim Z(\mathbb{C}[G])$  is equal to the number of conjugacy classes of  $G$ .  $\square$

**Example 2.10.** Let  $G = C_4$  be the cyclic group of order four. Then  $G$  has four simple modules and  $\mathbb{C}[G] \simeq \mathbb{C}^4$ .

**Example 2.11.** Let  $G = \mathbb{S}_3$ . Then  $G$  has three simple modules and

$$\mathbb{C}[G] \simeq \mathbb{C} \times \mathbb{C} \times M_2(\mathbb{C}).$$

**Open problem 2.1 (Brauer).** Which algebras are group algebras?

§2 Group algebras

This question might be impossible to answer, but it is extremely interesting. Examples 2.10 and 2.11 show that  $\mathbb{C}^4$  and  $\mathbb{C}^2 \times M_2(\mathbb{C})$  are complex group algebras.

**Exercise 2.12.** Is  $\mathbb{C}^2 \times M_2(\mathbb{C}) \times M_3(\mathbb{C})$  a complex group algebra?

## Lecture 3

**Definition 2.13.** An algebra  $A$  is **simple** if  $A \neq \{0\}$  and  $\{0\}$  and  $A$  are the only ideals of  $A$ .

**Proposition 2.14.** *Let  $A$  be a finite-dimensional simple algebra. There exists a non-zero left ideal  $I$  of minimal dimension. This ideal is a simple  $A$ -module, and every simple  $A$ -module is isomorphic to  $I$ .*

*Proof.* Since  $A$  is finite-dimensional and  $A$  is a left ideal of  $A$ , there exists a non-zero left ideal of minimal dimension. The minimality of  $\dim I$  implies that  $I$  is a simple  $A$ -module.

Let  $M$  be a simple  $A$ -module. In particular,  $M \neq \{0\}$ . Since

$$\text{Ann}_A(M) = \{a \in A : a \cdot M = \{0\}\}$$

is an ideal of  $A$  and  $1 \in A \setminus \text{Ann}_A(M)$ , the simplicity of  $A$  implies that  $\text{Ann}_A(M) = \{0\}$  and hence  $I \cdot M \neq \{0\}$  (because  $I \cdot m = 0$  for all  $m \in M$  yields  $I \subseteq \text{Ann}_A(M)$  and  $I$  is non-zero, a contradiction). Let  $m \in M$  be such that  $I \cdot m \neq \{0\}$ . The map

$$\varphi: I \rightarrow M, \quad x \mapsto x \cdot m,$$

is a module homomorphism. Since  $I \cdot m \neq \{0\}$ , the map  $\varphi$  is non-zero. Since both  $I$  and  $M$  are simple, Schur's lemma implies that  $\varphi$  is an isomorphism.  $\square$

If  $D$  is a division algebra, then  $M_n(D)$  is a simple algebra. The previous proposition implies that the algebra  $M_n(D)$  has a unique isomorphism class of simple modules. Each simple module is isomorphic to  $D^n$ .

**Proposition 2.15.** *Let  $A$  be a finite-dimensional algebra. If  $A$  is simple, then  $A$  is semisimple.*

*Proof.* Let  $S$  be the sum of the simple submodules appearing in the regular representation of  $A$ . We claim that  $S$  is an ideal of  $A$ . We know that  $S$  is a left ideal, as the submodules of the regular representation are exactly the left ideals of  $A$ . To show

that  $Sa \subseteq S$  for all  $a \in A$  we need to prove that  $Ta \subseteq S$  for all simple submodule  $T$  of  $A$  and  $a \in A$ . If  $T \subseteq A$  is a simple submodule and  $a \in A$ , let  $f: T \rightarrow Ta, t \mapsto ta$ . Since  $f$  is a surjective module homomorphism and  $T$  is simple, it follows that either  $\ker f = \{0\}$  or  $\ker f = T$ . If  $\ker f = T$ , then  $f(T) = Ta = \{0\} \subseteq S$ . If  $\ker f = \{0\}$ , then  $T \simeq f(T) = Ta$  and hence  $Ta$  is simple. Hence  $Ta \subseteq S$ .

Since  $S$  is an ideal of  $A$  and  $A$  is a simple algebra, it follows either  $S = \{0\}$  or  $S = A$ . Since  $S \neq \{0\}$ , because there exists a non-zero left ideal  $I$  of  $A$  such that  $I \neq \{0\}$  is of minimal dimension, it follows that  $S = A$ , that is, the regular representation of  $A$  is semisimple (because it is a sum of simple submodules). Therefore  $A$  is semisimple.  $\square$

**Theorem 2.16 (Wedderburn).** *Let  $A$  be a finite-dimensional algebra. If  $A$  is simple, then  $A \simeq M_n(D)$  for some  $n \in \mathbb{Z}_{>0}$  and some division algebra  $D$ .*

*Proof.* Since  $A$  is simple, it follows that  $A$  is semisimple. Artin–Wedderburn theorem implies that  $A \simeq \prod_{i=1}^k M_{n_i}(D_i)$  for some  $n_1, \dots, n_k$  and some division algebras  $D_1, \dots, D_k$ . Moreover,  $A$  has  $k$  isomorphism classes of simple modules. Since  $A$  is simple,  $A$  has only one isomorphism class of simple modules. Thus  $k = 1$  and hence  $A \simeq M_n(D)$  for some  $n \in \mathbb{Z}_{>0}$  and some division algebra  $D$ .  $\square$

### §3. Primitive rings

We will consider (possibly non-unitary) rings. Thus a **ring** is an abelian group  $R$  with an associative multiplication  $(x, y) \mapsto xy$  such that  $(x + y)z = xz + yz$  and  $x(y + z) = xy + xz$  for all  $x, y, z \in R$ . If there is an element  $1 \in R$  such that  $x1 = 1x = x$  for all  $x \in R$ , we say that  $R$  is a **unitary ring**. A **subring**  $S$  of  $R$  is an additive subgroup of  $R$  closed under multiplication.

**Example 3.1.**  $\mathbb{Z}$  is a (unitary) ring and  $2\mathbb{Z} = \{2m : m \in \mathbb{Z}\}$  is a (non-unitary) ring.

A **left ideal** (resp. **right ideal**) is a subring  $I$  of  $R$  such that  $rI \subseteq I$  (resp.  $Ir \subseteq I$ ) for all  $r \in R$ . An **ideal** (also two-sided ideal) of  $R$  is a subring  $I$  of  $R$  that is both a left and a right ideal of  $R$ .

**Example 3.2.** If  $I$  and  $J$  are both ideals of  $R$ , then the sum  $I + J = \{x + y : x \in I, y \in J\}$  and the intersection  $I \cap J$  are both ideals of  $R$ . The product  $IJ$ , defined as the additive subgroup of  $R$  generated by  $\{xy : x \in I, y \in J\}$ , is also an ideal of  $R$ .

**Example 3.3.** If  $R$  is a ring, the set  $Ra = \{xa : x \in R\}$  is a left ideal of  $R$ . Similarly, the set  $aR = \{ax : x \in R\}$  is a right ideal of  $R$ . The set  $RaR$ , which is defined as the additive subgroup of  $R$  generated by  $\{xay : x, y \in R\}$ , is an ideal of  $R$ .

**Example 3.4.** If  $R$  is a unitary ring, then  $Ra$  is the left ideal generated by  $a$ ,  $aR$  is the right ideal generated by  $a$  and  $RaR$  is the ideal generated by  $a$ . If  $R$  is not unitary, the left ideal generated by  $a$  is  $Ra + \mathbb{Z}a$ , the right ideal generated by  $a$  is  $aR + \mathbb{Z}a$  and the ideal generated by  $a$  is  $RaR + Ra + aR + \mathbb{Z}a$ .

§3 Primitive rings

The following exercise asks to prove the **Chinese Remainder Theorem** for arbitrary rings.

**Exercise 3.5.** Let  $R$  be a ring and  $I_1, \dots, I_n$  be ideals such that  $I_j + I_k = R$  whenever  $j \neq k$  and  $R = I_j + R^2$  for all  $j$ . Prove that

$$R/(I_1 \cap \dots \cap I_n) \simeq R/I_1 \times \dots \times R/I_n.$$

In the previous exercise, the condition  $R = I_j + R^2$  trivially holds in the case of rings with one.

**Definition 3.6.** A ring  $R$  is said to be **simple** if  $R^2 \neq \{0\}$  and the only ideals of  $R$  are  $\{0\}$  and  $R$ .

The condition  $R^2 \neq \{0\}$  is trivially satisfied in the case of rings with identity, as  $1 \in R^2 = \{r_1 r_2 : r_1, r_2 \in R\}$ .

**Example 3.7.** Division rings are simple.

Let  $S$  be a unitary ring. Recall that  $M_n(S)$  is the ring of  $n \times n$  square matrices with entries in  $S$ . If  $A = (a_{ij}) \in M_n(S)$  and  $E_{ij}$  is the matrix such that  $(E_{ij})_{kl} = \delta_{ik} \delta_{jl}$ , then

$$E_{ij} A E_{kl} = a_{jk} E_{il} \quad (3.1)$$

for all  $i, j, k, l \in \{1, \dots, n\}$ .

**Example 3.8.** If  $D$  is a division ring, then  $M_n(D)$  is simple.

Let  $R$  be a ring. A left  $R$ -module (or module, for short) is an abelian group  $M$  together with a map  $R \times M \rightarrow M$ ,  $(r, m) \mapsto r \cdot m$ , such that

$$(r+s) \cdot m = r \cdot m + s \cdot m, \quad r \cdot (m+n) = r \cdot m + r \cdot n, \quad r \cdot (s \cdot m) = (rs) \cdot m$$

for all  $r, s \in R$ ,  $m, n \in M$ . If  $R$  has an identity  $1$  and  $1 \cdot m = m$  holds for all  $m \in M$ , the module  $M$  is said to be **unitary**. If  $M$  is a unitary module, then  $M = R \cdot M$ .

**Exercise 3.9.** Let  $R$  be a simple unitary ring.

- 1) Prove that the center  $Z(R)$  of  $R$  is a field.
- 2) Prove that  $R$  is an algebra over  $Z(R)$ .

**Definition 3.10.** A module  $M$  is said to be **simple** if  $R \cdot M \neq \{0\}$  and the only submodules of  $M$  are  $\{0\}$  and  $M$ . If  $M$  is a simple module, then  $M \neq \{0\}$ .

If  $R$  is a unitary ring and  $M$  is a simple module, then  $M$  is unitary.

**Lemma 3.11.** Let  $M$  be a non-zero module. Then  $M$  is simple if and only if  $M = R \cdot m$  for all  $0 \neq m \in M$ .

*Proof.* Assume that  $M$  is simple. Let  $m \neq 0$ . Since  $R \cdot m$  is a submodule of the simple module  $M$ , either  $R \cdot m = \{0\}$  or  $R \cdot m = M$ . Let  $N = \{n \in M : R \cdot n = \{0\}\}$ . Since  $N$  is a submodule of  $M$  and  $R \cdot M \neq \{0\}$ ,  $N = \{0\}$ . Therefore  $R \cdot m = M$ , as  $m \neq 0$ . Now assume that  $M = R \cdot m$  for all  $m \neq 0$ . Let  $L$  be a non-zero submodule of  $M$  and let  $0 \neq x \in L$ . Then  $M = L$ , as  $M = R \cdot x \subseteq L$ .  $\square$

**Example 3.12.** Let  $D$  be a division ring and let  $V$  be a non-zero vector space (over  $D$ ). If  $R = \text{End}_D(V)$ , then  $V$  is a simple  $R$ -module with  $fv = f(v)$ ,  $f \in R$ ,  $v \in V$ .

**Example 3.13.** Let  $n \geq 2$ . If  $D$  is a division ring and  $R = M_n(D)$ , then each

$$I_k = \{(a_{ij}) \in R : a_{ij} = 0 \text{ for } j \neq k\}$$

is an  $R$ -module isomorphic to  $D^n$ . Thus  $M_n(D)$  is a simple ring that is not a simple  $M_n(D)$ -module.

**Definition 3.14.** A left ideal  $L$  of a ring  $R$  is said to be **minimal** if  $L \neq \{0\}$  and  $L$  does not strictly contain other left ideals of  $R$ .

Similarly one defines right minimal ideals and minimal ideals.

**Example 3.15.** Let  $D$  be a division ring and let  $R = M_n(D)$ . Then  $L = RE_{11}$  is a minimal left ideal.

**Example 3.16.** Let  $L$  be a non-zero left ideal. If  $RL \neq \{0\}$ , then  $L$  is minimal if and only if  $L$  is a simple  $R$ -module.

**Definition 3.17.** A left (resp. right) ideal  $L$  of  $R$  is said to be **regular** if there exists  $e \in R$  such that  $r - re \in L$  (resp.  $r - er \in L$ ) for all  $r \in R$ .

If  $R$  is a ring with identity, every left (or right) ideal is regular.

**Definition 3.18.** A left (resp. right) ideal  $I$  of  $R$  is said to be **maximal** if  $I \neq R$  and  $I$  is not properly contained in any other left (resp. right) ideal of  $R$ .

Similarly, one defines maximal ideals.

A standard application of Zorn's lemma proves that every unitary ring contains a maximal left (or right) ideal.

**Proposition 3.19.** Let  $R$  be a ring and  $M$  be a module. Then  $M$  is simple if and only if  $M \simeq R/I$  for some maximal regular left ideal  $I$ .

*Proof.* Assume that  $M$  is simple. Then  $M = R \cdot m$  for some  $m \neq 0$  by Lemma 3.11. The map  $\phi: R \rightarrow M, r \mapsto r \cdot m$ , is a surjective homomorphism of  $R$ -modules, so the first isomorphism theorem implies that  $M \simeq R/\ker \phi$ . Since  $\ker \phi$  is an ideal of  $R$ , it is in particular a left ideal of  $R$ .

We claim that  $I = \ker \phi$  is a maximal left ideal. The correspondence theorem and the simplicity of  $M$  imply that  $I$  is a maximal left ideal (because each left ideal  $J$  such that  $I \subseteq J$  yields a submodule of  $R/I$ ).

### §3 Primitive rings

We claim that  $I$  is regular. Since  $M = R \cdot m$ , there exists  $e \in R$  such that  $m = e \cdot m$ . If  $r \in R$ , then  $r - re \in I$  since  $\phi(r - re) = \phi(r) - \phi(re) = r \cdot m - r \cdot (e \cdot m) = 0$ .

Now assume that  $I$  is a maximal left ideal that is regular. The correspondence theorem implies that  $R/I$  has no non-zero proper submodules.

We claim that  $R \cdot (R/I) \neq 0$ . If  $R \cdot (R/I) = \{0\}$  and  $r \in R$ , then the regularity of  $I$  implies that there exists  $e \in R$  such that  $r - re \in I$ . Hence  $r \in I$ , as

$$0 = r \cdot (e + I) = re + I = r + I,$$

a contradiction to the maximality of  $I$ . □

Let  $R$  be a ring and  $M$  be a left  $R$ -module. For a subset  $N \subseteq M$  we define the **annihilator** of  $N$  as the subset

$$\text{Ann}_R(N) = \{r \in R : r \cdot n = 0 \text{ for all } n \in N\}.$$

**Example 3.20.**  $\text{Ann}_{\mathbb{Z}}(\mathbb{Z}/n) = n\mathbb{Z}$ .

**Exercise 3.21.** Let  $R$  be a ring and  $M$  be a module. If  $N \subseteq M$  is a subset, then  $\text{Ann}_R(N)$  is a left ideal of  $R$ . If  $N \subseteq M$  is a submodule of  $R$ , then  $\text{Ann}_R(N)$  is an ideal of  $R$ .

**Definition 3.22.** A module  $M$  is said to be **faithful** if  $\text{Ann}_R(M) = \{0\}$ .

**Example 3.23.** If  $K$  is a field, then  $K^n$  is a faithful unitary  $M_n(K)$ -module.

**Example 3.24.** If  $V$  is vector space over a field  $K$ , then  $V$  is faithful unitary  $\text{End}_K(V)$ -module.

**Definition 3.25.** A ring  $R$  is said to be **primitive** if there exists a faithful simple  $R$ -module.

Since we are considering left modules, our definition of primitive rings is that of left primitive rings. By convention, a primitive ring will always mean a left primitive ring. The use of right modules yields to the notion of right primitive rings.

**Exercise 3.26.** If  $R$  is a simple unitary ring, then  $R$  is primitive.

**Exercise 3.27.** If  $R$  is a commutative ring (maybe without identity), then  $R$  is primitive if and only if  $R$  is a field.

**Example 3.28.** The ring  $\mathbb{Z}$  is not primitive.

**Definition 3.29.** An ideal  $P$  of a ring  $R$  is said to be **primitive** if  $P = \text{Ann}_R(M)$  for some simple  $R$ -module  $M$ .

**Lemma 3.30.** Let  $R$  be a ring and  $P$  be an ideal of  $R$ . Then  $P$  is primitive if and only if  $R/P$  is a primitive ring.

*Proof.* Assume that  $P = \text{Ann}_R(M)$  for some  $R$ -module  $M$ . Then  $M$  is a simple  $(R/P)$ -module with

$$(r + P) \cdot m = r \cdot m,$$

$r \in R, m \in M$ . This operation is well-defined, as  $P = \text{Ann}_R(M)$ . Since  $M$  is a simple  $R$ -module, it follows that  $M$  is a simple  $(R/P)$ -module. Moreover,  $\text{Ann}_{R/P} M = \{0\}$ . Indeed, if  $(r + P) \cdot M = \{0\}$ , then  $r \in \text{Ann}_R M = P$  and hence  $r + P = P$ .

Assume now that  $R/P$  is primitive. Let  $M$  be a faithful simple  $(R/P)$ -module. Then  $r \cdot m = (r + P) \cdot m, r \in R, m \in M$ , turns  $M$  into an  $R$ -module. It follows that  $M$  is simple and that  $P = \text{Ann}_R(M)$ .  $\square$

**Example 3.31.** Let  $R_1, \dots, R_n$  be primitive rings and  $R = R_1 \times \dots \times R_n$ . Then each  $P_i = R_1 \times \dots \times R_{i-1} \times \{0\} \times R_{i+1} \times \dots \times R_n$  is a primitive ideal of  $R$  since  $R/P_i \simeq R_i$ .

**Lemma 3.32.** Let  $R$  be a ring. If  $P$  is a primitive ideal, there exists a regular maximal left ideal  $I$  such that  $P = \{x \in R : xR \subseteq I\}$ . Conversely, if  $I$  is a regular maximal left ideal, then  $\{x \in R : xR \subseteq I\}$  is a primitive ideal.

*Proof.* Assume that  $P = \text{Ann}_R(M)$  for some simple  $R$ -module  $M$ . By Proposition 3.19, there exists a regular maximal left ideal  $I$  such that  $M \simeq R/I$ . Then  $P = \text{Ann}_R(R/I) = \{x \in R : xR \subseteq I\}$ .

Conversely, let  $I$  be a regular maximal left ideal. By Proposition 3.19,  $R/I$  is a simple  $R$ -module. Then

$$\text{Ann}_R(R/I) = \{x \in R : xR \subseteq I\}$$

is a primitive ideal.  $\square$

**Exercise 3.33.** Maximal ideals of unitary rings are primitive.

**Exercise 3.34.** Prove that every primitive ideal of a commutative ring is maximal.

**Exercise 3.35.** Prove that  $M_n(R)$  is primitive if and only if  $R$  is primitive.

## Lecture 4

### §4. Jacobson's radical

**Definition 4.1.** Let  $R$  be a ring. The **Jacobson radical**  $J(R)$  is the intersection of all the annihilators of simple left  $R$ -modules. If  $R$  does not have simple left  $R$ -modules, then  $J(R) = R$ .

From the definition, it follows that  $J(R)$  is an ideal. Moreover,

$$J(R) = \bigcap \{P : P \text{ left primitive ideal}\}.$$

If  $I$  is an ideal of  $R$  and  $n \in \mathbb{Z}_{>0}$ ,  $I^n$  is the additive subgroup of  $R$  generated by the set  $\{y_1 \dots y_n : y_j \in I\}$ .

**Definition 4.2.** An ideal  $I$  of  $R$  is **nilpotent** if  $I^n = \{0\}$  for some  $n \in \mathbb{Z}_{>0}$ .

Similarly, one defines right or left nilpotent ideals. Note that an ideal  $I$  is nilpotent if and only if there exists  $n \in \mathbb{Z}_{>0}$  such that  $x_1 x_2 \dots x_n = 0$  for all  $x_1, \dots, x_n \in I$ .

**Definition 4.3.** An element  $x$  of a ring is said to be **nil** (or nilpotent) if  $x^n = 0$  for some  $n \in \mathbb{Z}_{>0}$ .

**Definition 4.4.** An ideal  $I$  of a ring is said to be **nil** if every element of  $I$  is nil.

Similarly, one defines right or left nil ideals. Note that every nilpotent ideal is nil, as  $I^n = 0$  implies  $x^n = 0$  for all  $x \in I$ .

**Example 4.5.** Let  $R = \mathbb{C}[X_1, X_2, \dots] / (X_1, X_2^2, X_3^3, \dots)$ . The ideal  $I = (X_1, X_2, X_3, \dots)$  is nil in  $R$ , as it is generated by nilpotent element. However, it is not nilpotent. Indeed, if  $I$  is nilpotent, then there exists  $k \in \mathbb{Z}_{>0}$  such that  $I^k = 0$  and hence  $x_i^k = 0$  for all  $i$ , a contradiction since  $x_{k+1}^k \neq 0$ .

**Proposition 4.6.** Let  $R$  be a ring. Then every nil left ideal (resp. right ideal) is contained in  $J(R)$ .

*Proof.* Assume that there is a nil left ideal (resp. right ideal)  $I$  such that  $I \not\subseteq J(R)$ . There exists a simple  $R$ -module  $M$  such that  $n = x \cdot m \neq 0$  for some  $x \in I$  and some  $m \in M$ . Since  $M$  is simple,  $R \cdot n = M$  and hence there exists  $r \in R$  such that

$$(rx) \cdot m = r \cdot (x \cdot m) = r \cdot n = m \quad (\text{resp. } (xr) \cdot n = x \cdot (r \cdot n) = x \cdot m = n).$$

Thus  $(rx)^k \cdot m = m$  (resp.  $(xr)^k \cdot n = n$ ) for all  $k \geq 1$ , a contradiction since  $rx \in I$  (resp.  $xr \in I$ ) is a nilpotent element.  $\square$

**Definition 4.7.** Let  $R$  be a ring. An element  $a \in R$  is said to be **left quasi-regular** if there exists  $r \in R$  such that  $r + a + ra = 0$ . Similarly,  $a$  is said to be **right quasi-regular** if there exists  $r \in R$  such that  $a + r + ar = 0$ .

Let  $R$  be a ring. A direct calculation shows that

$$R \times R \rightarrow R, \quad (r, s) \mapsto r \circ s = r + s + rs,$$

is an associative operation with neutral element 0. To show an explicit example, let  $R = \mathbb{Z}/3 = \{0, 1, 2\}$ . The multiplication table for the circle operation is

$$\begin{array}{c|ccc} \circ & 0 & 1 & 2 \\ \hline 0 & 0 & 1 & 2 \\ 1 & 1 & 0 & 2 \\ 2 & 2 & 2 & 2 \end{array}$$

If  $R$  is unitary, an element  $x \in R$  is left quasi-regular (resp. right quasi-regular) if and only if  $1 + x$  is left invertible (resp. right invertible). In fact, if  $r \in R$  is such that  $r + x + rx = 0$ , then  $(1 + r)(1 + x) = 1 + r + x + rx = 1$ . Conversely, if there exists  $y \in R$  such that  $y(1 + x) = 1$ , then

$$(y - 1) \circ x = y - 1 + x + (y - 1)x = 0.$$

**Example 4.8.** If  $x \in R$  is a nilpotent element, then  $y = \sum_{n \geq 1} x^n \in R$  is left quasi-regular. In fact, if there exists  $N$  such that  $x^N = 0$ , then the sum defining  $y$  is finite and  $y + (-x) + y(-x) = 0$ . Is right quasi-regular?

**Definition 4.9.** A left ideal  $I$  of  $R$  is said to be **left quasi-regular** (resp. right quasi-regular) if every element of  $I$  is left quasi-regular (resp. right quasi-regular). A left ideal is said to be **quasi-regular** if it is left and right quasi-regular.

Similarly one defines right quasi-regular ideals and quasi-regular ideals.

**Lemma 4.10.** Let  $I$  be a left ideal of  $R$ . If  $I$  is left quasi-regular, then  $I$  is quasi-regular.

*Proof.* Let  $x \in I$ . Let us prove that  $x$  is right quasi-regular. Since  $I$  is left quasi-regular, there exists  $r \in R$  such that  $r \circ x = r + x + rx = 0$ . Since  $r = -x - rx \in I$ , there exists  $s \in R$  such that  $s \circ r = s + r + sr = 0$ . Then  $s$  is right quasi-regular and

$$x = 0 \circ x = (s \circ r) \circ x = s \circ (r \circ x) = s \circ 0 = s. \quad \square$$

The following result uses Zorn's lemma.

**Lemma 4.11.** *Let  $R$  be a ring, and  $x \in R$  be an element that is not left quasi-regular. Then there exists a maximal left ideal  $M$  such that  $x \notin M$ . Moreover,  $R/M$  is a simple  $R$ -module and  $x \notin \text{Ann}_R(R/M)$ .*

*Proof.* Let  $T = \{r + rx : r \in R\}$ . A straightforward calculation shows that  $T$  is a left ideal of  $R$  such that  $x \notin T$  (if  $x \in T$ , then  $r + rx = -x$  for some  $r \in R$ , a contradiction since  $x$  is not left quasi-regular).

The only left ideal of  $R$  containing  $T \cup \{x\}$  is  $R$ . Indeed, if there exists a left ideal  $U$  containing  $T$ , then  $x \notin U$ , since otherwise every  $r \in R$  could be written as  $r = (r + rx) + r(-x) \in U$ .

Let  $\mathcal{S}$  be the set of proper left ideals of  $R$  containing  $T$  partially ordered by inclusion. If  $\{K_i : i \in I\}$  is a chain in  $\mathcal{S}$ , then  $K = \cup_{i \in I} K_i$  is an upper bound for the chain ( $K$  is a proper, as  $x \notin K$ ). Zorn's lemma implies that  $\mathcal{S}$  admits a maximal element  $M$ . Thus  $M$  is a maximal left ideal such that  $x \notin M$ .

Moreover,  $M$  is regular since  $r - r(-x) \in T \subseteq M$  for all  $r \in R$ . Therefore  $R/M$  is a simple  $R$ -module by Proposition 3.19. Since  $x \cdot (x + M) \neq 0$  (if  $x^2 \in M$ , then  $x \in M$ , as  $x + x^2 \in T \subseteq M$ ), it follows that  $x \notin \text{Ann}_R(R/M)$ .  $\square$

If  $x \in R$  is not left quasi-regular, the lemma implies that there exists a simple  $R$ -module  $M$  such  $x \notin \text{Ann}_R(M)$ . Thus  $x \notin J(R)$ .

**Theorem 4.12.** *Let  $R$  be a ring and  $x \in R$ . The following statements are equivalent:*

- 1) *The left ideal generated by  $x$  is quasi-regular.*
- 2)  *$Rx$  is quasi-regular.*
- 3)  *$x \in J(R)$ .*

*Proof.* The implication (1)  $\implies$  (2) is trivial, as  $Rx$  is included in the left ideal generated by  $x$ .

We now prove (2)  $\implies$  (3). If  $x \notin J(R)$ , by definition, there exists a simple  $R$ -module  $M$  such that  $x \cdot m \neq 0$  for some  $m \in M$ . The simplicity of  $M$  implies that  $(Rx) \cdot m = M$ . Thus there exists  $r \in R$  such that  $(rx) \cdot m = -m$ . There is an element  $s \in R$  such that  $s + rx + s(rx) = 0$  and hence

$$-m = (rx) \cdot m = (-s - srx) \cdot m = -s \cdot m + s \cdot m = 0,$$

a contradiction.

Finally, to prove (3)  $\implies$  (1), it is enough to note that  $x$  is left quasi-regular. If  $x \in J(R)$ , then  $x$  is left quasi-regular by the previous lemma. Thus the left ideal generated by  $x$  is quasi-regular by Lemma 4.10.  $\square$

The theorem immediately implies the following corollary.

**Corollary 4.13.** *If  $R$  is a ring, then  $J(R)$  is a quasi-regular ideal that contains every quasi-regular left ideal.*

The following result is somewhat what we all had in mind. We first need a lemma.

**Lemma 4.14.** *Let  $R$  be such that  $J(R) \neq R$ . If  $I$  is a left quasi-regular left ideal of  $R$ , then  $I \subseteq J(R)$ .*

*Proof.* Assume that  $I \not\subseteq J(R)$ . There exists a simple  $R$ -module  $N$  such that  $I \cdot N \neq \{0\}$ . In particular,  $I \cdot n \neq \{0\}$  for some  $0 \neq n \in N$ . Since  $I$  is a left ideal,  $I \cdot n$  is a non-zero submodule of  $N$ . Then  $I \cdot n = N$ , as  $N$  is simple. There exists  $x \in I$  such that  $x \cdot n = -n$ . Since  $I$  is left quasi-regular, there exists  $r \in R$  such that  $r + x + rx = 0$ . Thus

$$0 = 0 \cdot n = (r + x + rx) \cdot n = r \cdot n + x \cdot n + (rx) \cdot n = r \cdot n - n - r \cdot n = -n,$$

a contradiction.  $\square$

The following exercise uses Zorn's lemma and will be used in the proof of Theorem 4.16.

**Exercise 4.15.** Let  $R$  be a ring. Prove that every proper left ideal of  $R$  that is regular is contained in a maximal ideal that is regular.

**Theorem 4.16.** *Let  $R$  be a ring such that  $J(R) \neq R$ . Then*

$$J(R) = \bigcap \{I : I \text{ regular maximal left ideal of } R\}.$$

*Proof.* Let

$$K = \bigcap \{I : I \text{ regular maximal left ideal of } R\}.$$

Let us prove that  $K \subseteq J(R)$ . By Lemma 4.14, it is enough to prove that  $K$  is left quasi-regular. Let  $a \in K$  and  $T = \{r + ra : r \in R\}$ . If  $T = R$ , then  $-a = r + ra$  for some  $r \in R$  and hence  $a$  is left quasi-regular. So we need to prove that  $T = R$ . Note that  $T$  is a regular left ideal with  $e = -a$  (see Definition 3.17). If  $T \neq R$ , then  $T$  is contained in a maximal left ideal  $J$  by the previous exercise. Then  $a \in K \subseteq J$  and hence  $ra \in J$  for all  $r \in R$ . Since  $r + ra \in T \subseteq J$  for all  $r \in R$ , it follows that  $J = R$ , a contradiction. Therefore  $T = R$ .

Now we prove that  $J(R) \subseteq K$ . By Proposition 3.19,

$$J(R) = \bigcap \{\text{Ann}_R(R/I) : I \text{ regular maximal left ideal of } R\}.$$

Let  $I$  be a regular maximal left ideal. If  $r \in J(R) \subseteq \text{Ann}_R(R/I)$ , then, since  $I$  is regular, there exists  $e \in R$  such that  $r - re \in I$ . Since

$$re + I = r(e + I) = \{0\},$$

$re \in I$  and hence  $r \in I$ . Thus  $J(R) \subseteq K$ .  $\square$

**Example 4.17.** Each maximal ideals of  $\mathbb{Z}$  is of the form  $p\mathbb{Z} = \{pm : m \in \mathbb{Z}\}$  for some prime number  $p$ . Thus  $J(\mathbb{Z}) = \bigcap_p p\mathbb{Z} = \{0\}$ .

We now review some basic results useful to compute radicals.

**Proposition 4.18.** *Let  $\{R_i : i \in I\}$  be a family of rings. Then*

$$J\left(\prod_{i \in I} R_i\right) = \prod_{i \in I} J(R_i).$$

*Proof.* Let  $R = \prod_{i \in I} R_i$  and  $x = (x_i)_{i \in I} \in R$ . The left ideal  $Rx$  is quasi-regular if and only if each left ideal  $R_i x_i$  is quasi-regular in  $R_i$ , as  $x$  is quasi-regular in  $R$  if and only if each  $x_i$  is quasi-regular in  $R_i$ . Thus  $x \in J(R)$  if and only if  $x_i \in J(R_i)$  for all  $i \in I$ .  $\square$

For the next result, we shall need a lemma.

**Lemma 4.19.** *Let  $R$  be a ring and  $x \in R$ . If  $-x^2$  is a left quasi-regular element, then so is  $x$ .*

*Proof.* Let  $r \in R$  be such that  $r + (-x^2) + r(-x^2) = 0$  and  $s = r - x - rx$ . Then  $x$  is left quasi-regular, as

$$\begin{aligned} s + x + sx &= (r - x - rx) + x + (r - x - rx)x \\ &= r - x - rx + x + rx - x^2 - rx^2 = r - x^2 - rx^2 = 0. \end{aligned} \quad \square$$

**Proposition 4.20.** *If  $I$  is an ideal of  $R$ , then  $J(I) = I \cap J(R)$ .*

*Proof.* Note that  $I \cap J(R)$  is an ideal of  $I$ . Let  $x \in I \cap J(R)$  and  $r \in R$ . Since  $rx$  is left quasi-regular in  $R$ , there exists  $s \in R$  such that  $s + rx + sr = 0$ . Since  $s = -rx - sr \in I$ ,  $rx$  is left quasi-regular in  $I$ . Thus  $I \cap J(R) \subseteq J(I)$ .

Let  $x \in J(I) \subseteq I$  and  $r \in R$ . Since  $-(rx)^2 = (-rxr)x \in I(J(I)) \subseteq J(I)$ , the element  $-(rx)^2$  is left quasi-regular in  $I$ . Thus  $rx$  is left quasi-regular by Lemma 4.19.  $\square$

## Lecture 5

**Definition 4.21.** A ring  $R$  is said to be **radical** if  $J(R) = R$ .

**Example 4.22.** If  $R$  is a ring, then  $J(R)$  is a radical ring, by Proposition 4.20.

**Example 4.23.** The Jacobson radical of  $\mathbb{Z}/8$  is  $\{0, 2, 4, 6\}$ .

There are several characterizations of radical rings.

**Theorem 4.24.** *Let  $R$  be a ring. The following statements are equivalent:*

- 1)  $R$  is radical.
- 2)  $R$  admits no simple  $R$ -modules.
- 3)  $R$  does not have regular maximal left ideals.
- 4)  $R$  does not have primitive left ideals.
- 5) Every element of  $R$  is quasi-regular.
- 6)  $(R, \circ)$  is a group.

**Exercise 4.25.** Prove Theorem 4.24.

**Example 4.26.** Let

$$A = \left\{ \frac{2x}{2y+1} : x, y \in \mathbb{Z} \right\}.$$

Then  $A$  is a radical ring, as the inverse of the element  $\frac{2x}{2y+1}$  with respect to the circle operation  $\circ$  is

$$\left( \frac{2x}{2y+1} \right)' = \frac{-2x}{2(x+y)+1}.$$

### §5. Commutative rings with no maximal ideals

There are rings with no maximal ideals.

**Exercise 5.1.** Prove that the additive group of rational numbers is an abelian group with no maximal subgroups.

One can turn the additive group  $\mathbb{Q}$  of rational into a non-unitary ring by considering the zero multiplication  $xy = 0$  for all  $x, y \in \mathbb{Q}$ . This ring has no maximal ideals.

**Exercise 5.2.** Let  $R$  be a commutative ring and  $I$  be an ideal of  $R$ . Prove that  $I$  is maximal if and only if  $R/I$  is a field or a ring isomorphic to  $\mathbb{Z}/p$  with zero multiplication for some prime number  $p$ .

**Exercise 5.3.** Let  $R$  be a commutative ring. Prove that  $J(R)$  equals the intersection of maximal ideals such that  $R/M$  is a field.

Recall that the **characteristic of a ring** is defined as the least positive integer  $n$  such that  $nx = 0$  for all  $x$ . If no such  $n$  exists, then we say that the ring is of characteristic zero.

**Exercise 5.4.** Let  $R$  be a ring such and  $p$  be a prime number. If  $px = 0$  for all  $x \in R$ , then  $R$  has characteristic  $p$ .

We now characterize commutative rings with no maximal ideals. The result appeared in [6].

**Theorem 5.5 (Henriksen).** *Let  $R$  be a commutative ring. Then  $R$  has no maximal ideals if and only if  $J(R) = R$  and  $R^2 + pR = R$  for all prime number  $p$ .*

*Proof.* Assume first that  $R$  has no maximal ideals. Then  $J(R) = R$  by Exercise 5.3. Let  $p$  be a prime number such that  $I = R^2 + pR \neq R$ . Then  $I$  is a proper ideal of  $R$ . Let  $\pi: R \rightarrow R/I$  be the canonical map. Since  $R^2 \subseteq I$ ,  $0 = \pi(xy) = \pi(x)\pi(y)$  for all  $x, y \in R$ . Thus  $R/I$  has zero multiplication. Moreover, by Exercise 5.4,  $R/I$  has characteristic  $p$ , as  $pR \subseteq I$ . Thus  $R/I$  is a vector space over the field  $\mathbb{Z}/p$ . Let  $\{x_\alpha : \alpha \in \Lambda\}$  be a basis of  $R/I$ . Every element  $x \in R/I$  can be written uniquely as a finite sum of the form  $x = \sum \lambda_\alpha x_\alpha$  for scalars  $\lambda_\alpha$ . Let  $A$  be the ring with underlying additive group  $\mathbb{Z}/p$  and zero multiplication. For a fixed  $\beta \in \Lambda$ , the map

$$\gamma: R/I \rightarrow A, \quad x = \sum \lambda_\alpha x_\alpha \mapsto \lambda_\beta$$

is a ring homomorphism. The composition  $f = \gamma\pi: R \rightarrow R/I \rightarrow A$  is a ring homomorphism. By Exercise 5.2,  $\ker f$  is a maximal ideal, a contradiction.

Conversely, let  $M$  be a maximal ideal of  $R$ . If  $R/M$  is a field, then  $J(R) \subseteq M \neq R$ , a contradiction. By Exercise 5.2, there exists a prime number  $p$  such that  $R/M \simeq \mathbb{Z}/p$  as abelian groups and zero multiplication (i.e.  $xy \in M$  for all  $x, y \in R$ ). Let us write  $A$  to denote this ring and  $\pi: R \rightarrow R/M$  be the canonical map. Note that  $R^2 \subseteq M$ . Moreover,  $pR \subseteq M$ , as  $\pi(px) = p\pi(x) = 0$  for all  $x \in R$ . Thus  $R^2 + pR \subseteq M \neq R$ , a contradiction.  $\square$

We now present a non-trivial concrete example of a ring with no maximal ideals. For that purpose, we will use the field of fractions  $\mathbb{R}(X)$  of the real polynomial ring  $\mathbb{R}[X]$ .

**Exercise 5.6.** Let  $R$  be the set of rational real functions of the form  $f(X)/g(X)$ , where  $f(X), g(X) \in \mathbb{R}(X)$  and  $g(0) \neq 0$ . Prove the following statements:

- 1)  $R$  is an integral domain with a unique maximal ideal  $M = XR$ .
- 2)  $M$  has no maximal ideals.

**Definition 5.7.** A ring  $R$  is said to be **nil** if for every  $x \in R$  there exists  $n = n(x)$  such that  $x^n = 0$ .

**Exercise 5.8.** Prove that a nil ring is a radical ring.

**Exercise 5.9.** Let  $\mathbb{R}[[X]]$  be the ring of power series with real coefficients. Prove that the ideal  $X\mathbb{R}[[X]]$  consisting of power series with zero constant term is a radical ring that is not nil.

**Theorem 5.10.** If  $R$  is a ring, then  $J(R/J(R)) = \{0\}$ .

*Proof.* If  $R$  is radical, the result is trivial. Suppose then that  $J(R) \neq R$ . Let  $M$  be a simple  $R$ -module. Then  $M$  is a simple module over  $R/J(R)$  with

$$(x + J(R)) \cdot m = x \cdot m, \quad x \in R, m \in M.$$

If  $x + J(R) \in J(R/J(R))$ , then  $x \cdot M = (x + J(R)) \cdot M = \{0\}$ . Then  $x \in J(R)$ , as  $x$  annihilates any simple module over  $R$ .  $\square$

**Theorem 5.11.** Let  $R$  be a ring and  $n \in \mathbb{Z}_{>0}$ . Then  $J(M_n(R)) = M_n(J(R))$ .

*Proof.* We first prove that  $J(M_n(R)) \subseteq M_n(J(R))$ . If  $J(R) = R$ , the theorem is clear. Let us assume that  $J(R) \neq R$  and let  $J = J(R)$ . If  $M$  is a simple  $R$ -module, then  $M^n$  is a simple  $M_n(R)$ -module with the usual multiplication. Let  $x = (x_{ij}) \in J(M_n(R))$  and  $m_1, \dots, m_n \in M$ . Then

$$x \begin{pmatrix} m_1 \\ \vdots \\ m_n \end{pmatrix} = 0.$$

In particular,  $x_{ij} \in \text{Ann}_R(M)$  for all  $i, j \in \{1, \dots, n\}$ . Hence  $x \in M_n(J)$ .

We now prove that  $M_n(J) \subseteq J(M_n(R))$ . Let

$$J_1 = \begin{pmatrix} J & 0 & \cdots & 0 \\ J & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ J & 0 & \cdots & 0 \end{pmatrix} \quad \text{and} \quad x = \begin{pmatrix} x_1 & 0 & \cdots & 0 \\ x_2 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ x_n & 0 & \cdots & 0 \end{pmatrix} \in J_1.$$

Since  $x_1$  is quasi-regular, there exists  $y_1 \in R$  such that  $x_1 + y_1 + x_1 y_1 = 0$ . If

$$y = \begin{pmatrix} y_1 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 \end{pmatrix},$$

then  $u = x + y + xy$  is lower triangular, as

$$u = \begin{pmatrix} 0 & 0 & \cdots & 0 \\ x_2 y_1 & 0 & \cdots & 0 \\ x_3 y_1 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ x_n y_1 & 0 & \cdots & 0 \end{pmatrix}.$$

Since  $u^n = 0$ , the element

$$v = -u + u^2 - u^3 + \cdots + (-1)^{n-1} u^{n-1}$$

is such that  $u + v + uv = 0$ . Thus  $x$  is right quasi-regular, as

$$x + (y + v + yv) + x(y + v + yv) = 0,$$

and therefore  $J_1$  is right quasi-regular. Similarly one proves that each  $J_i$  is right quasi-regular and hence  $J_i \subseteq J(M_n(R))$  for all  $i \in \{1, \dots, n\}$ . In conclusion,

$$J_1 + \cdots + J_n \subseteq J(M_n(R))$$

and therefore  $M_n(J) \subseteq J(M_n(R))$ . □

**Exercise 5.12.** Let  $R$  be a unitary ring. Then

$$J(R) = \bigcap \{M : M \text{ is a left maximal ideal}\}.$$

**Exercise 5.13.** Let  $R$  be a unitary ring. The following statements are equivalent:

- 1)  $x \in J(R)$ .
- 2)  $x \cdot M = \{0\}$  for all simple  $R$ -module  $M$ .
- 3)  $x \in P$  for all primitive left ideal  $P$ .
- 4)  $1 + rx$  is invertible for all  $r \in R$ .
- 5)  $1 + \sum_{i=1}^n r_i x s_i$  is invertible for all  $n$  and all  $r_i, s_i \in R$ .
- 6)  $x$  belongs to every maximal ideal maximal.

The following exercise is entirely optional. It somewhat shows a recent application of radical rings to solutions of the celebrated Yang–Baxter equation.

**Exercise 5.14.** A pair  $(X, r)$  is a **solution** to the Yang–Baxter equation if  $X$  is a set and  $r: X \times X \rightarrow X \times X$  is a bijective map such that

$$(r \times \text{id}) \circ (\text{id} \times r) \circ (r \times \text{id}) = (\text{id} \times r) \circ (r \times \text{id}) \circ (\text{id} \times r).$$

The solution  $(X, r)$  is said to be **involutive** if  $r^2 = \text{id}$ . By convention, we write

$$r(x, y) = (\sigma_x(y), \tau_y(x)).$$

The solution  $(X, r)$  is said to be **non-degenerate** if  $\sigma_x: X \rightarrow X$  and  $\tau_x: X \rightarrow X$  are bijective for all  $x \in X$ .

- 1) Let  $X$  be a set and  $\sigma: X \rightarrow X$  be a bijective map. Prove that the pair  $(X, r)$ , where  $r(x, y) = (\sigma(y), \sigma^{-1}(x))$ , is an involutive non-degenerate solution.

Let  $R$  be a radical ring. For  $x, y \in R$  let

$$\begin{aligned}\lambda_x(y) &= -x + x \circ y = xy + y, \\ \mu_y(x) &= \lambda_x(y)' \circ x \circ y = (xy + y)'x + x\end{aligned}$$

Prove the following statements:

- 2)  $\lambda: (R, \circ) \rightarrow \text{Aut}(R, +)$ ,  $x \mapsto \lambda_x$ , is a group homomorphism.  
 3)  $\mu: (R, \circ) \rightarrow \text{Aut}(R, +)$ ,  $y \mapsto \mu_y$ , is a group antihomomorphism.  
 4) The map

$$r: R \times R \rightarrow R \times R, \quad r(x, y) = (\lambda_x(y), \mu_y(x)),$$

is an involutive non-degenerate solution to the Yang–Baxter equation.

**Exercise 5.15.** If  $D$  is a division ring and  $R = D[X_1, \dots, X_n]$ , then  $J(R) = \{0\}$ .

**Example 5.16.** A commutative and unitary ring  $R$  is **local** if it contains only one maximal ideal. If  $R$  is a local ring and  $M$  is its maximal ideal, then  $J(R) = M$ . Some particular cases:

- 1) If  $K$  is a field and  $R = K[[X]]$ , then  $J(R) = (X)$ .  
 2) If  $p$  is a prime number and  $R = \mathbb{Z}/p^n$ , then  $J(R) = (p)$ .

We finish the discussion on the Jacobson radical with some results in the case of unitary algebras. We first need an application of Zorn's lemma.

**Exercise 5.17.** Let  $I$  be a proper left ideal that is left regular. Prove that  $I$  is contained in a maximal left ideal which is regular.

**Proposition 5.18.** Let  $A$  be a  $K$ -algebra and  $I$  be a subset of  $A$ . Then  $I$  is a regular maximal left ideal of the algebra  $A$  if and only if  $I$  is a regular maximal left ideal of the ring  $A$ .

*Proof.* Let  $I$  be a left regular maximal ideal of the ring  $A$ . We claim that  $\lambda I \subseteq I$  for all  $\lambda \in K$ . Assume that  $\lambda I \not\subseteq I$  for some  $\lambda$ . Then  $I + \lambda I$  is an ideal of the ring  $A$  that contains  $I$ , as

$$a(I + \lambda I) = aI + a(\lambda I) \subseteq I + \lambda(aI) \subseteq I + \lambda I.$$

Since  $I$  is maximal, it follows that  $I + \lambda I = A$ . The left regularity of  $I$  implies that there exists  $e \in A$  such that  $a - ae \in I$  for all  $a \in A$ . Write  $e = x + \lambda y$  for  $x, y \in I$ . Then

$$e^2 = e(x + \lambda y) = ex + e(\lambda y) = ex + (\lambda e)y \in I.$$

Since  $e - e^2 \in I$  and  $e^2 \in I$ , it follows that  $e \in I$ . Thus  $A = I$ , as  $a - ae \in I$  for all  $a \in A$ , a contradiction.

Conversely, if  $I$  is a left regular maximal ideal of the algebra  $A$ , then  $I$  is a left regular ideal of the ring  $A$ . We claim that  $I$  is a maximal left ideal of the ring of  $A$ . There exists a regular maximal left ideal  $M$  of the ring  $A$  that contains  $I$ . Since  $M$  is regular, it follows that  $M$  is a regular maximal ideal of the algebra  $A$ . Thus  $M = I$  because  $I$  is a maximal left ideal of the algebra  $A$ .  $\square$

For algebras, the Jacobson radical of an algebra can be defined as the intersection of the left ideals (of the algebra) that are maximal and regular. The previous proposition then implies that the Jacobson radical of an algebra coincides with the Jacobson radical of the underlying ring.

## §6. Amitsur's theorem

We now prove an important result of Amitsur that has several interesting applications. We first need a lemma.

**Lemma 6.1.** *Let  $A$  be an algebra with one and let  $x \in J(A)$ . Then  $x$  is algebraic if and only if  $x$  is nilpotent.*

*Proof.* Since  $x$  is algebraic, there exist  $a_0, \dots, a_n \in K$  not all zero such that

$$a_0 + a_1x + \dots + a_nx^n = 0.$$

Let  $r$  be the smallest integer such that  $a_r \neq 0$ . Then

$$x^r(1 + b_1x + \dots + b_mx^m) = 0,$$

for some  $b_1, \dots, b_m \in K$ . Since  $1 + b_1x + \dots + b_mx^m$  is a unit by Exercise 5.13, it follows that  $x^r = 0$ .  $\square$

An application:

**Proposition 6.2.** *If  $A$  is an algebraic algebra with one, then  $J(A)$  is the largest nil ideal of  $A$ .*

*Proof.* The previous lemma implies that  $J(A)$  is a nil ideal. Proposition 4.6 now implies that  $J(A)$  is the largest nil ideal of  $A$ .  $\square$

**Theorem 6.3 (Amitsur).** *Let  $A$  be a  $K$ -algebra with one such that  $\dim_K A < |K|$  (as cardinals). Then  $J(A)$  is the largest nil ideal of  $A$ .*

## §7 Jacobson's conjecture

*Proof.* If  $K$  is finite, then  $A$  is a finite-dimensional algebra. In particular,  $A$  is algebraic and hence  $J(A)$  is a nil ideal by Proposition 6.2.

Assume that  $K$  is infinite and let  $a \in J(A)$ . Exercise 5.13 implies that every element of the form  $1 - \lambda^{-1}a$ ,  $\lambda \in K \setminus \{0\}$ , is invertible. Thus

$$a - \lambda = -\lambda(1 - \lambda^{-1}a)$$

is invertible for all  $\lambda \in K \setminus \{0\}$ . Let  $S = \{(a - \lambda)^{-1} : \lambda \in K \setminus \{0\}\}$ . Since

$$(a - \lambda)^{-1} = (a - \mu)^{-1} \iff \lambda = \mu,$$

it follows that  $|S| = |K \setminus \{0\}| = |K| > \dim_K A$ . Then  $S$  is linearly dependent, so there are  $\beta_1, \dots, \beta_n \in K$  not all zero and distinct elements  $\lambda_1, \dots, \lambda_n \in K$  such that

$$\sum_{i=1}^n \beta_i (a - \lambda_i)^{-1} = 0. \quad (5.1)$$

Multiplying (5.1) by  $\prod_{i=1}^n (a - \lambda_i)$  we get

$$\sum_{i=1}^n \beta_i \prod_{j \neq i} (a - \lambda_j) = 0.$$

We claim that  $a$  is algebraic over  $K$ . Indeed,

$$f(X) = \sum_{i=1}^n \beta_i \prod_{j \neq i} (X - \lambda_j)$$

is non-zero, as, for example, if  $\beta_1 \neq 0$ , then  $f(\lambda_1) = \beta_1 (\lambda_1 - \lambda_2) \cdots (\lambda_1 - \lambda_n) \neq 0$  and  $f(a) = 0$ . Since  $a \in J(A)$  is algebraic, it follows  $a$  is nilpotent by Lemma 6.1.  $\square$

Amitsur's theorem implies the following result.

**Corollary 6.4.** *Let  $K$  be a non-countable field. If  $A$  is an algebra over  $K$  with a countable basis, then  $J(A)$  is the largest nil ideal of  $A$ .*

## §7. Jacobson's conjecture

We now conclude the lecture with two big open problems related to the Jacobson radical. The first one is Jacobson's conjecture.

**Open problem 7.1 (Jacobson).** Let  $R$  be a noetherian ring. Is then

$$\bigcap_{n \geq 1} J(R)^n = \{0\}?$$

Open problem 7.1 was originally formulated by Jacobson in 1956 [10] for one-sided noetherian rings. In 1965 Herstein [7] found a counterexample in the case of one-sided noetherian rings and reformulated the conjecture as it appears here.

**Exercise 7.2 (Herstein).** Let  $D$  be the ring of rationals with odd denominators. Let  $R = \begin{pmatrix} D & \mathbb{Q} \\ 0 & \mathbb{Q} \end{pmatrix}$ . Prove that  $R$  is right noetherian and  $J(R) = \begin{pmatrix} J(D) & \mathbb{Q} \\ 0 & 0 \end{pmatrix}$ . Prove that  $J(R)^n \supseteq \begin{pmatrix} 0 & \mathbb{Q} \\ 0 & 0 \end{pmatrix}$  and hence  $\bigcap_n J(R)^n$  is non-zero.

## §8. Köthe's conjecture

The following problem is maybe the most important open problem in non-commutative ring theory.

**Open problem 8.1 (Köthe).** Let  $R$  be a ring. Is the sum of two arbitrary nil left ideals of  $R$  is nil?

Open problem 8.1 is the well-known Köthe's conjecture. The conjecture was first formulated in 1930, see [12]. It is known to be true in several cases. In full generality, the problem is still open. In [13] Krempa proved that the following statements are equivalent:

- 1) Köthe's conjecture is true.
- 2) If  $R$  is a nil ring, then  $R[X]$  is a radical ring.
- 3) If  $R$  is a nil ring, then  $M_2(R)$  is a nil ring.
- 4) Let  $n \geq 2$ . If  $R$  is a nil ring, then  $M_n(R)$  is a nil ring.

In 1956 Amitsur formulated the following conjecture, see for example [1]: If  $R$  is a nil ring, then  $R[X]$  is a nil ring. In [20] Smoktunowicz found a counterexample to Amitsur's conjecture. This counterexample suggests that Köthe's conjecture might be false. A simplification of Smoktunowicz's example appears in [17]. See [21, 22] for more information on Köthe's conjecture and related topics.

## Lecture 6

### §9. Gilmer's theorem

Hilbert's theorem states that if  $R$  is a noetherian commutative unitary ring, then  $R[X]$  is noetherian. Following [5], we now present the converse of Hilbert's theorem.

**Theorem 9.1 (Gilmer).** *Let  $R$  be a commutative ring. If  $R[X]$  is noetherian, then  $R$  is unitary.*

*Proof.* Let  $a \in R$ . For  $m \geq 0$ , let

$$\begin{aligned} I_m &= (a, aX, aX^2, \dots, aX^m) \\ &= R[X]a + R[X]aX + \dots + R[X]aX^m + \mathbb{Z}a + \mathbb{Z}aX + \dots + \mathbb{Z}aX^m. \end{aligned}$$

Then  $I_0 \subseteq I_1 \subseteq \dots \subseteq I_m \subseteq I_{m+1} \subseteq \dots$  is a sequence of ideals of  $R[X]$ . Since  $R[X]$  is noetherian,  $I_n = I_{n+1}$  for some  $n$ . In particular,  $aX^{n+1} \in I_{n+1} = I_n$ . Thus

$$aX^{n+1} = \sum_{i=1}^{n+1} aX^{i-1} f_i(X) + \sum_{i=1}^{n+1} k_i aX^{i-1}$$

for some  $f_1(X), \dots, f_n(X) \in R[X]$  and  $k_1, \dots, k_n \in \mathbb{Z}$ . Comparing the coefficient of  $X^{n+1}$  one gets that  $a = ar$  for some  $r \in R$ . Thus

$$\text{for every } a \in R \text{ there exists } r \in R \text{ such that } a = ra. \quad (6.1)$$

*Claim.* For every  $a_1, \dots, a_n \in R$  there exists  $r \in R$  such that  $a_i = ra_i$  for all  $i$ .

We proceed by induction on  $n$ . The case  $n = 1$  is (6.1). Assume that the result holds for  $n - 1 \geq 1$ . By the inductive hypothesis, there exists  $r_1 \in R$  such that  $a_i = r_1 a_i$  for all  $i \in \{1, \dots, n - 1\}$ . Moreover, there exists  $r_2 \in R$  such that  $a_n = r_2 a_n$ . Let  $r = r_1 + r_2 - r_1 r_2$ . Then

$$ra_n = r_1 a_n + r_2 a_n - r_1 r_2 a_n = r_1 a_n + a_n - r_1 a_n = a_n.$$

Moreover, for  $i \in \{1, \dots, n-1\}$ ,

$$ra_i = r_1a_i + r_2a_i - r_1r_2a_i = a_i + r_2a_i - r_2r_1a_i = a_i + r_2a_i - r_2a_i = a_i.$$

We now finish the proof of the theorem. Let  $R[X] \rightarrow R$ ,  $f(X) \mapsto f(0)$ , be an evaluation map. Since it is a surjective ring homomorphism,  $R$  is noetherian. In particular,  $R$  is finitely generated, say

$$R = (a_1, \dots, a_n) = Ra_1 + \dots + Ra_n + \mathbb{Z}a_1 + \dots + \mathbb{Z}a_n$$

for some  $a_1, \dots, a_n \in R$ .

We now prove that the element  $r$  from the claim we proved turns  $R$  into a unitary ring, that is  $r = 1_R$ . We need to show that  $rb = b$  for all  $b \in R$ . If  $b \in R$ , then

$$b = t_1a_1 + \dots + t_na_n + m_1a_1 + \dots + m_na_n$$

for some  $t_1, \dots, t_n \in R$  and  $m_1, \dots, m_n \in \mathbb{Z}$ . Since  $a_i = ra_i$  for all  $i \in \{1, \dots, n\}$ , it immediately follows that  $rb = b$ .  $\square$

**Example 9.2.** The polynomial ring  $(2\mathbb{Z})[X]$  is not noetherian, as the ring  $2\mathbb{Z}$  is not unitary.

## §10. Artinian modules

**Definition 10.1.** Let  $R$  be a ring. A module  $N$  is **artinian** if every decreasing sequence  $N_1 \supseteq N_2 \supseteq \dots$  of submodules of  $N$  stabilizes, that is there exists  $n \in \mathbb{Z}_{>0}$  such that  $N_n = N_{n+k}$  for all  $k \in \mathbb{Z}_{\geq 0}$ .

Let  $X$  be a set and  $\mathcal{S}$  be a set of subsets of  $X$ . We say that  $A \in \mathcal{S}$  is a **minimal element** of  $\mathcal{S}$  if there is no  $Y \in \mathcal{S}$  such that  $Y \subsetneq A$ .

**Proposition 10.2.** A module  $N$  is artinian if and only if every non-empty subset of submodules of  $N$  contains a minimal element.

*Proof.* Assume that  $N$  is artinian. Let  $\mathcal{S}$  be a non-empty set of submodules of  $N$ . Suppose that  $\mathcal{S}$  has no minimal element and let  $N_1 \in \mathcal{S}$ . Since  $N_1$  is not minimal, there exists  $N_2 \in \mathcal{S}$  such that  $N_1 \supsetneq N_2$ . Now assume the submodules

$$N_1 \supsetneq N_2 \supsetneq \dots \supsetneq N_k$$

we chosen. Since  $N_k$  is not minimal, there exists  $N_{k+1}$  such that  $N_k \supsetneq N_{k+1}$ . This procedure produces a sequence  $N_1 \supsetneq N_2 \supsetneq \dots$  that cannot stabilize, a contradiction.

If  $N_1 \supseteq N_2 \supseteq \dots$  is a sequence of submodules, then  $\mathcal{S} = \{N_j : j \geq 1\}$  has a minimal element, say  $N_n$ . Then  $N_n = N_{n+k}$  for all  $k$ .  $\square$

A module  $N$  is **noetherian** if for every sequence  $N_1 \subseteq N_2 \subseteq \dots$  of submodules of  $N$  there exists  $n \in \mathbb{Z}_{>0}$  such that  $N_n = N_{n+k}$  for all  $k \in \mathbb{Z}_{\geq 0}$ .

**Exercise 10.3.** Let  $M$  be a module. The following statements are equivalent:

- 1)  $M$  is noetherian.
- 2) Every submodule of  $M$  is finitely generated.
- 3) Every non-empty subset  $S$  of submodules of  $M$  contains a maximal element, that is an element  $X \in S$  such that there is no  $Z \in S$  such that  $X \subsetneq Z$ .

**Exercise 10.4.** Prove that a ring  $R$  is left noetherian if every sequence of left ideals  $I_1 \subseteq I_2 \subseteq \cdots$  stabilizes.

**Exercise 10.5.** Let

$$0 \longrightarrow A \xrightarrow{f} B \xrightarrow{g} C \longrightarrow 0$$

be an exact sequence of modules. Prove that  $B$  is noetherian (resp. artinian) if and only if  $A$  and  $C$  are noetherian (resp. artinian).

**Definition 10.6.** A ring  $R$  is **left artinian** if the module  ${}_R R$  is artinian.

Similarly one defines right artinian rings.

**Example 10.7.** The ring  $\mathbb{Z}$  is noetherian. It is not artinian, as the sequence

$$2\mathbb{Z} \supseteq 4\mathbb{Z} \supseteq 8\mathbb{Z} \supseteq \cdots$$

does not stabilize.

**Exercise 10.8.** Prove that a ring  $R$  is left artinian if every sequence of left ideals  $I_1 \supseteq I_2 \supseteq \cdots$  stabilizes.

**Definition 10.9.** A **composition series** of the module  $M$  is a sequence

$$\{0\} = M_0 \subsetneq M_1 \subsetneq M_2 \subsetneq \cdots \subsetneq M_n = M$$

of submodules of  $M$  such that each  $M_i/M_{i-1}$  is non-zero and has no non-zero proper submodules. In this case  $n$  is the length of the composition series.

The previous definition makes sense also for non-unitary rings. That is why it is required that each quotient  $M_i/M_{i-1}$  has no proper submodules.

**Theorem 10.10.** A non-zero module admits a composition series if and only if it is artinian and noetherian.

*Proof.* Let  $M$  be a non-zero module and let  $\{0\} = M_0 \subsetneq M_1 \subsetneq \cdots \subsetneq M_n = M$  be a composition series for  $M$ . We claim that each  $M_i$  is artinian and noetherian. We proceed by induction on  $i$ . The case  $i = 0$  is trivial. Let us assume that  $M_i$  is artinian and noetherian. Since  $M_i/M_{i+1}$  has no proper submodules and the sequence

$$0 \longrightarrow M_i \longrightarrow M_{i+1} \longrightarrow M_{i+1}/M_i \longrightarrow 0$$

is exact, it follows that  $M_{i+1}$  is artinian and noetherian, see Exercise 10.5.

Conversely, let  $M$  be a non-zero artinian and noetherian module. Let  $M_0 = \{0\}$  and  $M_1$  be minimal among the non-zero submodules of  $M$  (it exists by Proposition 10.2). If  $M_1 \neq M$ , let  $M_2$  be minimal among those submodules of  $M$  such that  $M_1 \subsetneq M_2$ . This procedure produces a sequence

$$\{0\} = M_0 \subsetneq M_1 \subsetneq M_2 \subsetneq \cdots$$

of submodules of  $M$ , where each  $M_{i+1}/M_i$  is non-zero and admits no proper submodules. Since  $M$  is noetherian, the sequence stabilizes and hence it follows that  $M_n = M$  for some  $n$ .  $\square$

**Definition 10.11.** Let  $M$  be a module. We say that the composition series

$$M = V_0 \supseteq V_1 \supseteq \cdots \supseteq V_k = \{0\}, \quad M = W_0 \supseteq W_1 \supseteq \cdots \supseteq W_l = \{0\},$$

are **equivalent** if  $k = l$  and there exists  $\sigma \in \mathbb{S}_k$  such that  $V_i/V_{i-1} \simeq W_{\sigma(i)}/W_{\sigma(i)-1}$  for all  $i \in \{1, \dots, k\}$ .

**Exercise 10.12.** Find all composition series for the  $\mathbb{Z}$ -module  $\mathbb{Z}/6$ .

**Theorem 10.13 (Jordan–Hölder).** Any two composition series for a module are equivalent.

*Proof.* Let  $M$  be a module and

$$M = V_0 \supseteq V_1 \supseteq \cdots \supseteq V_k = \{0\}, \quad M = W_0 \supseteq W_1 \supseteq \cdots \supseteq W_l = \{0\},$$

be composition series of  $M$ . We claim that these composition series are equivalent. We proceed by induction on  $k$ . The case  $k = 1$  is trivial, as in this case  $M$  has no proper submodules and  $M \supseteq \{0\}$  is the only possible composition series for  $M$ . So assume the result holds for modules with composition series of length  $< k$ . If  $V_1 = W_1$ , then  $V_1$  has composition series of lengths  $k - 1$  and  $l - 1$ . The inductive hypothesis implies that  $k = l$  and we are done. So assume that  $V_1 \neq W_1$ . Since  $V_1$  and  $W_1$  are submodules of  $M$ , the sum  $V_1 + W_1$  is also a submodule of  $M$ . Moreover,  $M/V_1$  has no non-zero proper submodules and hence  $V_1 + W_1 = V$ . Then

$$M/V_1 = \frac{V_1 + W_1}{V_1} \simeq \frac{V_1}{V_1 \cap W_1}.$$

Since  $V_1$  has a composition series,  $V_1$  is artinian and noetherian by Theorem 10.10. The submodule  $U = V_1 \cap W_1$  is also artinian and noetherian and hence, by Theorem 10.10, admits a composition series

$$U = U_0 \supseteq U_1 \supseteq \cdots \supseteq U_r = \{0\}.$$

Thus  $V_1 \supseteq \cdots \supseteq V_k = \{0\}$  and  $V_1 \supseteq U \supseteq U_1 \supseteq \cdots \supseteq U_r = \{0\}$  are both composition series for  $V_1$ . The inductive hypothesis implies that  $k - 1 = r + 1$  and that these composition series are equivalent. Similarly,

$$W_1 \supsetneq W_2 \supsetneq \cdots \supsetneq W_l = \{0\}, \quad W_1 \supsetneq U \supsetneq U_1 \supsetneq \cdots \supsetneq U_r = \{0\},$$

are both composition series for  $W_1$  and hence  $l - 1 = r + 1$  and these composition series are equivalent. Therefore  $l = k$  and the proof is completed.  $\square$

Jordan–Hölder theorem allows us to define the length of modules that admit a composition series.

**Definition 10.14.** Let  $M$  be a module with a composition series. The **length**  $\ell(M)$  of  $M$  is defined as the length of any composition series of  $M$ .

A module is said to be of finite length if it admits a composition series.

**Exercise 10.15.** If  $N$  and  $Q$  are modules with composition series and

$$0 \longrightarrow N \xrightarrow{f} M \xrightarrow{g} Q \longrightarrow 0$$

is an exact sequence of modules, then  $\ell(M) = \ell(N) + \ell(Q)$ .

**Exercise 10.16.** If  $A$  and  $B$  are finite-length submodules of  $M$ , then

$$\ell(A + B) + \ell(A \cap B) = \ell(A) + \ell(B).$$

**Theorem 10.17.** If  $R$  is a left artinian ring, then  $J(R)$  is nilpotent.

*Proof.* Let  $J = J(R)$ . Since  $R$  is a left artinian ring, the sequence  $(J^m)_{m \in \mathbb{Z}_{>0}}$  of left ideals stabilizes. There exists  $k \in \mathbb{Z}_{>0}$  such that  $J^k = J^l$  for all  $l \geq k$ . We claim that  $J^k = \{0\}$ . If  $J^k \neq \{0\}$  let  $\mathcal{S}$  the set of left ideals  $I$  such that  $J^k I \neq \{0\}$ . Since

$$J^k J^k = J^{2k} = J^k \neq \{0\},$$

the set  $\mathcal{S}$  is non-empty. Since  $R$  is left artinian,  $\mathcal{S}$  has a minimal element  $I_0$ . Since  $J^k I_0 \neq \{0\}$ , let  $x \in I_0 \setminus \{0\}$  be such that  $J^k x \neq \{0\}$ . Moreover,  $J^k x$  is a left ideal of  $R$  contained in  $I_0$  and such that  $J^k x \in \mathcal{S}$ , as  $J^k(J^k x) = J^{2k} x = J^k x \neq \{0\}$ . The minimality of  $I_0$  implies that,  $J^k x = I_0$ . In particular, there exists  $r \in J^k \subseteq J$  such that  $rx = x$ . Since  $-r \in J(R)$  is left quasi-regular, there exists  $s \in R$  such that  $s - r - sr = 0$ . Thus

$$x = rx = (s - sr)x = sx - s(rx) = sx - sx = 0,$$

a contradiction.  $\square$

**Corollary 10.18.** Let  $R$  be a left artinian ring. Each nil left ideal is nilpotent and  $J(R)$  is the unique maximal nilpotent ideal of  $R$ .

*Proof.* Let  $L$  be a nil left ideal of  $R$ . By Proposition 4.6,  $L$  is contained in  $J(R)$ . Thus  $L$  is nilpotent, as  $J(R)$  is nilpotent by Theorem 10.17.  $\square$

## §11. Akizuki's theorem

We now prove that if  $R$  is a unitary commutative artinian ring, then  $R$  is noetherian.

**Exercise 11.1.** Let  $R$  be a unitary commutative ring,  $I$  be an ideal of  $R$  and  $M$  be an  $R$ -module such that  $I \cdot M = \{0\}$ . Prove that if  $M$  is finitely generated, then  $M$  is a finitely generated  $(R/I)$ -module with

$$(r + I) \cdot m = r \cdot m, \quad r \in R, m \in M.$$

Recall that an ideal  $I$  of a commutative ring  $R$  is said to be **prime** if  $xy \in I$  implies that  $x \in I$  or  $y \in I$ .

**Exercise 11.2.** Let  $R$  be a unitary commutative artinian ring.

- 1) Prove that if  $R$  is a domain, then  $R$  is a field.
- 2) Prove that prime ideals of  $R$  are maximal.

**Theorem 11.3 (Akizuki).** Let  $R$  be a unitary commutative ring. If  $R$  is artinian, then  $R$  is noetherian.

*Proof.* Assume that the result is not true, so there exists an ideal of  $R$  that is not finitely generated. Let  $X$  be the set of ideals of  $R$  that are not finitely generated. Since  $X \neq \emptyset$  and  $R$  is artinian, there exists a minimal element  $I \in X$ . The minimality of  $I$  implies that if  $J$  is an ideal of  $R$  such that  $J \subsetneq I$ , then  $J$  is finitely generated.

*Claim.* Either  $RI = \{0\}$  or  $RI = I$ .

If not, let  $r \in R$  be such that  $rI \neq \{0\}$  and  $rI \neq I$ . Since  $rI$  is an ideal of  $R$  and  $rI \subsetneq I$ , the minimality of  $I$  implies that  $rI$  is finitely generated. Let  $f: I \rightarrow rI$ ,  $x \mapsto rx$ . Then  $f$  is a surjective module homomorphism. Since  $RI \neq \{0\}$ ,  $f$  is non-zero. In particular,  $\ker f$  is finitely generated, again by the minimality of  $I$ . By the first isomorphism theorem,  $I/\ker f \simeq rI$  as  $R$ -modules. Since  $\ker f$  and  $I/\ker f \simeq rI$  are finitely generated,  $I$  is finitely generated, a contradiction.

*Claim.*  $M = \{r \in R : rI = \{0\}\}$  is a maximal ideal of  $R$ .

Routine calculations show that  $M$  is an ideal. Since  $R$  is artinian, it is enough to show that  $M$  is a prime ideal. Let  $rs \in M$ . Then  $(rs)I = \{0\}$ . If  $r \notin M$ , then  $rI \neq \{0\}$ . By the previous claim,  $rI = I$ . Thus

$$\{0\} = (rs)I = s(rI) = sI$$

and hence  $s \in M$ .

Since  $M$  is maximal,  $K = R/M$  is a field. Since  $MI = \{0\}$ ,  $I$  is an  $(R/M)$ -module, that is  $I$  is a  $K$ -vector space. By Exercise 11.1,  $\dim_K I = \infty$ . Let  $B$  be a basis of  $I$  (as a  $K$ -vector space) and  $x_0 \in B$ . Let  $J$  be the subspace of  $I$  generated by  $B \setminus \{x_0\}$ . A direct calculation shows that  $J$  is an ideal of  $R$ . Since  $\dim_K J = \infty$ , it follows that  $J$  is not a finitely generated ideal of  $R$  (Exercise 11.1). This is a contradiction, because  $J$  is an ideal of  $R$  such that  $J \subsetneq I$ .  $\square$

## Lecture 7

### §12. Semiprimitive rings

**Definition 12.1.** A ring  $R$  is **semiprimitive** (or Jacobson semisimple) if  $J(R) = \{0\}$ .

In Lecture 3 we defined primitive rings as those rings that have a faithful simple module. We claim that primitive rings are semiprimitive. If  $R$  is primitive, then  $\{0\}$  is a primitive ideal. Since  $J(R)$  is the intersection of primitive ideals, it follows that  $J(R) = \{0\}$ .

**Example 12.2.** If  $R = \prod_{i \in I} R_i$  is a direct product of semiprimitive rings, then  $R$  is semiprimitive, as

$$J(R) = J\left(\prod_{i \in I} R_i\right) = \prod_{i \in I} J(R_i) = \{0\}.$$

**Example 12.3.**  $\mathbb{Z}$  is semiprimitive, as  $J(\mathbb{Z}) = \cap_p p\mathbb{Z} = \{0\}$ .

**Example 12.4.** Let  $R = C[a, b]$  be the ring of continuous maps  $f: [a, b] \rightarrow \mathbb{R}$ . In this case  $J(R)$  is the intersection of all maximal ideals of  $R$ . Note that each maximal ideal of  $R$  is of the form

$$U_c = \{f \in C[a, b] : f(c) = 0\}$$

for some  $c \in [a, b]$ . Thus  $J(R) = \cap_{a \leq c \leq b} U_c = \{0\}$ .

We proved in Theorem 5.10 (Lecture 4) that  $R/J(R)$  is semiprimitive.

**Definition 12.5.** Let  $\{R_i : i \in I\}$  be an arbitrary family of rings. For each  $j \in I$ , let  $\pi_j: \prod_{i \in I} R_i \rightarrow R_j$  be the canonical map. We say that  $R$  is a **subdirect product** of  $\{R_i : i \in I\}$  if the following conditions hold:

- 1) There exists an injective ring homomorphism  $f: R \rightarrow \prod_{i \in I} R_i$ .
- 2) For each  $j$ , the composition  $\pi_j f: R \rightarrow R_j$  is surjective.

Direct products and direct sums of rings are all examples of subdirect products of rings.

**Exercise 12.6.** Write (if possible)  $\mathbb{Z}$  as a non-trivial subdirect product.

**Example 12.7.** Let  $R$  be a ring,  $\{I_j : j\}$  be a collection of ideals of  $R$  and

$$f: R \rightarrow \prod_i R/I_i, \quad r \mapsto (r + I_i)_i.$$

For each  $i$ , let  $R_i = R/I_i$ . Then  $R$  is a subdirect product of the  $R_i$  if and only if  $f$  is injective.

**Theorem 12.8.** *Let  $R$  be a non-zero ring. Then  $R$  is semiprimitive if and only if  $R$  is isomorphic to a subdirect product of primitive rings.*

*Proof.* Suppose first that  $R$  is semiprimitive and let  $\{P_i : i \in I\}$  be the collection of primitive ideals of  $R$ . This collection is non-empty, as  $R$  is non-zero and semiprimitive. Each  $R/P_j$  is primitive and  $\{0\} = J(R) = \cap_{i \in I} P_i$ . For  $j$  let  $\lambda_j: R \rightarrow R/P_j$  and  $\pi_j: \prod_{i \in I} R/P_i \rightarrow R/P_j$  be canonical maps. The ring homomorphism

$$\phi: R \rightarrow \prod_{i \in I} R/P_i, \quad r \mapsto \{\lambda_i(r) : i \in I\},$$

is injective and satisfies  $\pi_j \phi(R) = R/P_j$  for all  $j$ .

Assume now that  $R$  is isomorphic to a subdirect product of primitive rings  $R_j$  and let  $\varphi: R \rightarrow \prod_{i \in I} R_i$  be an injective homomorphism such that  $\pi_j(\varphi(R)) = R_j$  for all  $j$ . For  $j$  let  $P_j = \ker \pi_j \varphi$ . Since  $R/P_j \simeq R_j$ , each  $P_j$  is a primitive ideal. If  $x \in \cap_{i \in I} P_i$ , then  $\varphi(x) = 0$  and thus  $x = 0$ . Hence  $J(R) \subseteq \cap_{i \in I} P_i = 0$ .  $\square$

**Example 12.9.** The ring  $C[a, b]$  of Example 12.4 is isomorphic to a subdirect product of the fields  $C[a, b]/U_c \simeq \mathbb{R}$ .

### §13. Jacobson's density theorem

At this point, it is convenient to recall that modules over division rings are pretty much as vector spaces over fields. Modules over division rings are usually called vector spaces over division rings.

**Definition 13.1.** Let  $D$  be a division ring, and  $V$  be a vector space over  $D$ . A subring  $R \subseteq \text{End}_D(V)$  is a **dense ring of linear operators** of  $V$  (or simple, **dense** in  $V$ ) if for every  $n \in \mathbb{Z}_{>0}$ , every linearly independent set  $\{u_1, \dots, u_n\} \subseteq V$  and every (not necessarily linearly independent) subset  $\{v_1, \dots, v_n\} \subseteq V$  there exists  $f \in R$  such that  $f(u_j) = v_j$  for all  $j \in \{1, \dots, n\}$ .

**Proposition 13.2.** *Let  $D$  be a division ring and  $V$  be a finite-dimensional  $D$ -vector space. Then  $\text{End}_D(V)$  is the only dense ring of  $V$ .*

*Proof.* Let  $R$  be dense in  $V$  and let  $\{v_1, \dots, v_n\}$  be a basis of  $V$ . By definition,  $R \subseteq \text{End}_D(V)$ . If  $g \in \text{End}_D(V)$  then, since  $R$  is dense in  $V$ , there exists  $f \in R$  such that  $f(v_j) = g(v_j)$  for all  $j \in \{1, \dots, n\}$ . Hence  $g = f \in R$ .  $\square$

**Theorem 13.3 (Jacobson).** *A ring  $R$  is primitive if and only if it is isomorphic to a dense ring on a vector space over a division ring.*

We shall need the following lemma.

**Lemma 13.4.** *Let  $D$  be a division ring and  $V$  be a  $D$ -vector space. If  $R$  is dense in  $V$  and  $I$  is a non-zero ideal of  $R$ , then  $I$  is dense on  $V$ .*

*Proof.* Fix  $n \in \mathbb{Z}_{>0}$ . Let  $\{u_1, \dots, u_n\} \subseteq V$  be a linearly independent set and let  $\{v_1, \dots, v_n\} \subseteq V$ . We want to find  $\gamma \in I$  such that  $\gamma(u_i) = v_i$  for all  $i$ . Since  $I \neq \{0\}$ , there exists  $h \in I \setminus \{0\}$ . This means that  $h(u) = v \neq 0$  for some  $u \neq 0$ . Since  $R$  is dense on  $V$ , there exist  $g_1, \dots, g_n \in R$  such that

$$g_i(u_j) = \begin{cases} u & \text{if } i = j, \\ 0 & \text{otherwise.} \end{cases}$$

Further, since  $\{v\}$  is a linearly independent subset of  $V$ , there exist  $f_1, \dots, f_n \in R$  such that  $f_i(v) = v_i$  for all  $i$ . Thus  $\gamma = \sum_{i=1}^n f_i h g_i \in I$  is such that  $\gamma(u_j) = v_j$  for all  $j \in \{1, \dots, n\}$ .  $\square$

Now we are ready to prove Jacobson's density theorem.

*Proof of Theorem 13.3.* If  $R$  is isomorphic to a dense ring in  $V$ , where  $V$  is a  $D$ -vector space for some division ring  $D$ , then  $R$  is primitive, as  $V$  is a simple and faithful  $R$ -module. Why faithful? If  $f \in \text{Ann}_R(V)$ , then  $f = 0$  since  $f(v) = 0$  for all  $v \in V$ . Why simple? If  $W \subseteq V$  is a non-zero submodule, let  $v \in V$  and  $w \in W \setminus \{0\}$ . There exists  $f \in R$  such that  $v = f(w) \in W$ .

Now assume that  $R$  is primitive. Let  $V$  be a simple faithful module. Schur's lemma implies that  $D = \text{End}_R(V)$  is a division ring. Thus  $V$  is a  $D$ -vector space with

$$D \times V \rightarrow V, \quad (\delta, v) \mapsto \delta v = \delta(v).$$

For  $r \in R$  let

$$\gamma_r: V \rightarrow V, \quad v \mapsto rv.$$

A straightforward calculation shows that  $\gamma_r \in \text{End}_D(V)$  and that  $\gamma: R \rightarrow \text{End}_D(V)$ ,  $r \mapsto \gamma_r$ , is a ring homomorphism. Since  $V$  is faithful,  $R \simeq \gamma(R) = \{\gamma_r : r \in R\}$ . In fact, if  $\gamma_r = \gamma_s$ , then  $rv = \gamma_r(v) = \gamma_s(v) = sv$  for all  $v \in V$  and hence  $r = s$ , as  $(r - s)v = 0$  for all  $v \in V$ .

*Claim.* If  $U$  is a finite-dimensional subspace of  $V$ , for each  $w \in V \setminus U$  there exists  $r \in R$  such that  $\gamma_r(U) = \{0\}$  and  $\gamma_r(w) \neq 0$ .

Suppose the claim is not true. Let  $U$  be a counterexample of minimal dimension. Then  $\dim_D U \geq 1$ , as the claim holds for the zero subspace. (For this, we only need to show that for each non-zero  $v \in V$ , there exists  $r \in R$  such that  $rv \neq 0$ . Since  $V$  is simple,  $V = (v)$ . If  $rv = 0$  for all  $r \in R$ , then  $V = \{0\}$ , a contradiction to the simplicity of  $V$ .) Let now  $U_0$  be a subspace of  $U$  such that  $\dim U_0 = \dim U - 1$  and let

$$L = \{l \in R : \gamma_l(U_0) = \{0\}\}.$$

The minimality of the dimension of  $U$  shows that the claim is true for  $U_0$ , so any  $v \in V \setminus U_0$  is such that  $Lv = V$ . Since there exists  $l \in L$  such that  $lv = \gamma_l(v) \neq 0$  and  $L$  is a left ideal of  $R$ , it follows that  $Lv \subseteq V$  is a submodule and the claim follows from the simplicity of  $V$ .

Let  $w \in V \setminus U$  be such that the claim is not true. Let  $u \in U \setminus U_0$ . The map

$$\delta: V \rightarrow V, \quad v \mapsto lw,$$

where  $v = lu \in Lu = V$  (that depends both on  $u$  and  $w$ ) is well-defined: if  $l_1, l_2 \in L$  are such that  $v = l_1u = l_2u$ , then  $(l_1 - l_2)u = 0$  and thus

$$0 = (l_1 - l_2)w = l_1w - l_2w,$$

as for all  $r \in R$ , if  $rU = \{0\}$ , then  $rw = 0$ . Further,  $\delta$  is a homomorphism of modules over  $R$ , as if  $l \in L$  is such that  $v = lu$ , then

$$\delta(rv) = \delta(r(lu)) = \delta((rl)u) = (rl)w = r(lw) = r\delta(v)$$

for all  $r \in R$ .

For every  $l \in L$ ,

$$l(\delta(u) - w) = l\delta(u) - lw = \delta(lu) - lw = 0.$$

Thus  $L(\delta(u) - w) = \{0\}$ . This implies that  $\delta(u) - w \notin V \setminus U_0$ , that is  $\delta(u) - w \in U_0$ . Therefore

$$w = \delta(u) - (\delta(u) - w) \in Du + U_0 = U,$$

a contradiction.

Now the theorem follows from the claim. Let  $u_1, \dots, u_n \in V$  be linearly independent vectors and let  $v_1, \dots, v_n \in V$  arbitrary vectors. Fix  $i \in \{1, \dots, n\}$ . The previous claim with

$$U = \langle u_1, \dots, u_{i-1}, u_{i+1}, \dots, u_n \rangle$$

and  $w = u_i$  implies that there exists  $r_i \in R$  such that  $\gamma_{r_i}(u_j) = 0$  if  $j \neq i$  and  $\gamma_{r_i}(u_i) \neq 0$ . Since there exists  $s_i \in R$  such that  $\gamma_{s_i}\gamma_{r_i}(u_i) = v_i$ , it follows that  $r = \sum_{j=1}^n s_j r_j \in R$  is such that  $\gamma_r(u_i) = v_i$  for all  $i \in \{1, \dots, n\}$ .  $\square$

**Corollary 13.5.** *If  $R$  is a primitive ring, then either there exists a division ring  $D$  such that  $R \simeq \text{End}_D(V)$  for some finite-dimensional vector space  $V$  over  $D$  or for*

§13 Jacobson's density theorem

*all  $m \in \mathbb{Z}_{>0}$  there exists a subring  $R_m$  of  $R$  and a surjective ring homomorphism  $R_m \rightarrow \text{End}_D(V_m)$  for some vector space  $V_m$  over  $D$  such that  $\dim_D V_m = m$ .*

*Proof.* The ring  $R$  admits a simple faithful module  $V$ . Furthermore, by Jacobson's density theorem we may assume that there exists a division ring  $D$  such that  $R$  is dense in a vector space  $V$  over  $D$ . Let  $\gamma: R \rightarrow \text{End}_D(V)$ ,  $r \mapsto \gamma_r$ , where  $\gamma_r(v) = rv$ . Since  $V$  is faithful,  $\gamma$  is injective. Thus  $R \simeq \gamma(R)$ .

If  $\dim_D V < \infty$ , the result follows from Proposition 13.2. Assume that  $\dim_D V = \infty$  and let  $\{u_1, u_2, \dots\}$  be a linearly independent set. For each  $m \in \mathbb{Z}_{>0}$  let  $V_m$  be the subspace generated by  $\{u_1, \dots, u_m\}$  and  $R_m = \{r \in R : rV_m \subseteq V_m\}$ . Then  $R_m$  is a subring of  $R$ . Since  $R$  is dense in  $V$ , the map

$$R_m \rightarrow \text{End}_D(V_m), \quad r \mapsto \gamma_r|_{V_m}$$

is a surjective ring homomorphism. □

## Lecture 8

### §14. Prime rings

In commutative algebra, domains play a fundamental role. In non-commutative algebra, certain things could be quite different. For example, the ring  $M_n(\mathbb{C})$  is not a domain. We need a non-commutative generalization of domains.

**Definition 14.1.** Let  $R$  be a ring (not necessarily with one). Then  $R$  is **prime** if for  $x, y \in R$  such that  $xRy = \{0\}$  it follows that  $x = 0$  or  $y = 0$ .

A ring  $R$  is a **domain** if  $xy = 0$  implies  $x = 0$  or  $y = 0$ . Each domain is trivially a prime ring.

**Example 14.2.** A commutative ring is prime if and only if it is a domain, as  $ab = 0$  if and only if  $aRb = \{0\}$ .

**Example 14.3.** A non-zero ideal of a prime ring is a prime ring.

**Exercise 14.4.** A ring is a domain if and only if it is both prime and reduced.

A characterization of prime rings:

**Proposition 14.5.** Let  $R$  be a ring. The following statements are equivalent:

- 1)  $R$  is prime.
- 2) If  $I$  and  $J$  are left ideals such that  $IJ = \{0\}$ , then  $I = \{0\}$  or  $J = \{0\}$ .
- 3) If  $I$  and  $J$  are ideals such that  $IJ = \{0\}$ , then  $I = \{0\}$  or  $J = \{0\}$ .

*Proof.* We first prove that 1)  $\implies$  2). Let  $I$  and  $J$  be left ideals such that  $IJ = \{0\}$ . Then  $IRJ = I(RJ) \subseteq IJ = \{0\}$ . If  $J \neq \{0\}$ ,  $u \in I$  and  $v \in J \setminus \{0\}$ , then  $uRv \in IRJ = \{0\}$ . Hence  $u = 0$ .

The implication 2)  $\implies$  3) is trivial.

Let us prove that 3)  $\implies$  1). Let  $x, y \in R$  be such that  $xRy = \{0\}$ . Let  $I = RxR$  and  $J = RyR$ . Since  $IJ = (RxR)(RyR) \subseteq R(xRy)R = \{0\}$ , we may assume that  $I = \{0\}$ . In particular,  $Rx$  and  $xR$  are ideals, as  $R(xR) = (Rx)R = \{0\}$ . Then  $\mathbb{Z}x$  is an ideal of  $R$  such that  $(\mathbb{Z}x)R = \{0\}$ . Thus  $x = 0$ .  $\square$

Simple rings are trivially prime. The converse is not true. For example,  $\mathbb{Z}$  is a domain, so it is a prime ring but is not simple.

**Example 14.6.** If  $R_1$  and  $R_2$  are rings,  $R = R_1 \times R_2$  is not prime, as  $I = R_1 \times \{0\}$  and  $J = \{0\} \times R_2$  are non-zero ideals such that  $IJ = \{0\}$ .

**Theorem 14.7 (Connel).** *Let  $K$  be a field of characteristic zero and  $G$  be a group. Then  $K[G]$  is prime if and only if  $G$  does not contain non-trivial finite normal subgroups.*

*Proof.* See for example [18, Theorem 2.10 of Chapter 4].  $\square$

**Lemma 14.8.** *Let  $R$  be a prime ring and  $L$  be a minimal left ideal of  $R$ . Then  $R$  is primitive.*

*Proof.* Since  $L$  is a minimal left ideal, it is simple as a module over  $R$ . We claim that  $L$  is faithful. Let  $y \in L \setminus \{0\}$  and  $x \in \text{Ann}_R(L)$ . Since  $xRy \in xRL \subseteq xL = \{0\}$ , it follows that  $x = 0$ .  $\square$

**Lemma 14.9.** *Let  $D$  be a division ring and  $R$  be a dense ring in a module  $V$  over  $D$ . If  $R$  is left artinian, then  $\dim_D V < \infty$ .*

*Proof.* Assume that  $\dim_D V = \infty$  and let  $\{u_1, u_2, \dots\}$  be linearly independent. Since  $R \subseteq \text{End}_D(V)$ , it follows that  $V$  is a module over  $R$  with  $f \cdot v = f(v)$ , where  $f \in R$  and  $v \in V$ . For  $n \in \mathbb{Z}_{>0}$  let

$$I_n = \text{Ann}_R(\{u_1, \dots, u_n\}).$$

Each  $I_j$  is a left ideal of  $R$  and  $I_1 \supseteq I_2 \supseteq \dots \supseteq I_n \supseteq \dots$ . Let  $n \in \mathbb{Z}_{>0}$  and  $v \in V \setminus \{0\}$ . Since  $R$  is dense in  $V$ , there exists  $f \in R$  such that  $f(u_j) = 0$  for all  $j \in \{1, \dots, n\}$  and  $f(u_{n+1}) = v \neq 0$ . Thus  $I_1 \supseteq I_2 \supseteq \dots \supseteq I_n \supseteq \dots$ , a contradiction.  $\square$

**Theorem 14.10 (Wedderburn).** *Let  $R$  be a left artinian ring. The following statements are equivalent:*

- 1)  $R$  is simple.
- 2)  $R$  is prime.
- 3)  $R$  is primitive.
- 4)  $R \simeq M_n(D)$  for some  $n$  and some division ring  $D$ .

*Proof.* The implication 1)  $\implies$  2) is trivial.

To show that 2)  $\implies$  3) first note that  $R$  contains a minimal left ideal, as  $R$  is left artinian. By Lemma 14.8,  $R$  is primitive.

Now we prove that 3)  $\implies$  4). If  $R$  is primitive, Jacobson's density theorem implies that there exists a division ring  $D$  such that  $R$  is isomorphic to a ring  $S$  that is dense in a vector space  $V$  over  $D$ . Since  $R$  is left artinian, Lemma 14.9 implies that  $R = \text{End}_D(V) \simeq M_n(D)$ , as  $\dim_D V < \infty$ .

Finally, 4)  $\implies$  1) is trivial, as  $M_n(D)$  is simple.  $\square$

We now prove Artin–Wedderburn theorem. We will assume that our ring is a unitary left artinian ring. One could prove Artin–Wedderburn’s theorem for arbitrary rings –see for example [9]– but when dealing with unitary rings, the proof is simpler. We will prove that left artinian semiprimitive unitary rings are isomorphic to a direct product of finitely many matrix rings. The idea of the proof goes as follows. We know that if  $R$  is semiprimitive, then  $R$  is a subdirect product of primitive rings; that is there exists an injective map

$$R \rightarrow \prod_{i \in I} R/I_i$$

where each  $I_i$  is a primitive ideal. Since  $R$  is left artinian, the set  $I$  will be finite. Moreover, by Wedderburn’s theorem,  $R/I_i \simeq M_{n_i}(D_i)$  for some division ring  $D_i$ . Finally, a non-commutative version of the Chinese remainder theorem implies that the map is fact surjective.

**Definition 14.11.** An ideal  $I$  of  $R$  is **prime** if  $xRy \subseteq I$  implies  $x \in I$  or  $y \in I$ .

Note that a ring  $R$  is prime if and only if  $\{0\}$  is a prime ideal. Moreover, an ideal  $I$  of ring  $R$  is prime if and only if the ring  $R/I$  is prime.

**Lemma 14.12.** *If  $R$  is left artinian and  $I$  is a primitive ideal, then  $I$  is prime.*

*Proof.* Since  $I$  is primitive, then  $R/I$  is primitive. By Wedderburn theorem,  $R/I$  is prime and hence  $I$  is prime.  $\square$

**Theorem 14.13 (Artin–Wedderburn).** *Let  $R$  be a semiprimitive left artinian unitary ring. Then  $R \simeq \prod_{i=1}^k M_{n_i}(D_i)$  for finitely many division rings  $D_1, \dots, D_k$ .*

We shall need the following lemmas.

**Lemma 14.14.** *Let  $R$  be a left artinian ring and  $I$  be a primitive ideal. Then  $I$  is maximal.*

*Proof.* If  $I$  is a primitive ideal of  $R$ , then  $R/I$  is a primitive ring by Lemma 3.30. By Wedderburn’s theorem,  $R/I$  is simple. Thus  $I$  is maximal by Proposition 3.19.  $\square$

**Lemma 14.15.** *Let  $R$  be a left artinian unitary ring. Let  $I_1, \dots, I_k$  be finitely many distinct maximal ideals of  $R$ . Then  $I_2 \cdots I_k \not\subseteq I_1$ .*

*Proof.* Suppose the result is not true and let  $k$  be minimal such that  $I_2 \cdots I_k \subseteq I_1$ . Since the result is clearly true for two distinct maximal ideals,  $k \geq 3$ . Let  $I = I_2 \cdots I_{k-1}$ . Since  $I \not\subseteq I_1$ , there exists  $x \in I \setminus I_1$ . Moreover, there exists  $y \in I_k \setminus I_1$ , as  $I_k \neq I_1$ . Then  $(xR)y \subseteq II_k \subseteq I_1$ . Note that  $I_1$  is prime: if  $xy \in xRy \subseteq I_1$  and  $x \notin I_1$ , then  $(x, M) = R$ . Thus  $1 = rx + m$  for some  $r \in R$  and  $m \in M$ . By multiplying by  $y$  on the left,  $y = r(xy) + my \in M$ . Now that we know that  $I_1$  is prime, it follows that either  $x \in I_1$  or  $y \in I_1$ , a contradiction.  $\square$

**Lemma 14.16.** *Let  $R$  be a left artinian unitary ring. Then  $R$  has only finitely many primitive ideals.*

*Proof.* If  $I_1, I_2, \dots$  are infinitely many primitive ideals. Since  $R$  is left artinian, the sequence  $I_1 \supseteq I_1 I_2 \supseteq \dots$  stabilizes, so there exists  $n$  such that

$$I_1 I_2 \cdots I_n = I_1 I_2 \cdots I_n I_{n+1} \subseteq I_{n+1}.$$

This contradicts the previous lemma, as each  $I_j$  is a maximal ideal.  $\square$

Now we are ready to prove the theorem.

*Proof of Theorem 14.13.* Let  $I_1, \dots, I_k$  be the (distinct) primitive ideals of  $R$ . We know that each  $I_i$  is a maximal ideal. Thus  $I_i + I_j = R$  for  $i \neq j$ . Since  $R$  is semiprimitive,  $I_1 \cap \dots \cap I_k = J(R) = \{0\}$ . Let

$$\varphi: R \rightarrow \prod_{i=1}^k R/I_i, \quad x \mapsto (x + I_1, \dots, x + I_k).$$

Then  $\varphi$  is a ring homomorphism with kernel  $I_1 \cap \dots \cap I_k = \{0\}$ , so  $\varphi$  is injective. We need to prove that  $\varphi$  is surjective.

We first claim that  $I_1 + (I_2 \cdots I_k) = R$ . In fact, since  $I_1, \dots, I_k$  are maximal ideals,  $I_2 \cdots I_k \not\subseteq I_1$ . This implies that  $I_1 + (I_2 \cdots I_k)$  is an ideal of  $R$  that contains  $I_1$ . Since  $I_1$  is maximal,  $I_1 + (I_2 \cdots I_k) = R$ .

Since  $I_1 + (I_2 \cdots I_k) = R$ , there exists  $x_1 \in \prod_{j=2}^k I_j$  such that  $1 \in x_1 + I_1$ . Note that  $x_1 = (1 + I_1) \cap (I_2 \cdots I_k) \subseteq I_j$  for all  $j \in \{2, \dots, k\}$ . Thus

$$\varphi(x_1) = (x + I_1, x + I_2, \dots, x + I_k) = (1 + I_1, I_2, \dots, I_k).$$

Similarly, there exists  $x_2 \in 1 + I_2, \dots, x_k \in 1 + I_k$  such that

$$\begin{aligned} \varphi(x_2) &= (I_1, 1 + I_2, \dots, I_k), \\ &\vdots \\ \varphi(x_k) &= (I_1, I_2, \dots, 1 + I_k). \end{aligned}$$

From this, it follows that  $\varphi$  is surjective. Each  $R/I_i$  is primitive and hence isomorphic to  $M_{n_i}(D_i)$  for some  $n_i$  and some division ring  $D_i$ . Therefore

$$R \simeq R/I_1 \times \cdots \times R/I_k \simeq \prod_{i=1}^k M_{n_i}(D_i). \quad \square$$

## §15. Semisimple modules

In the first lectures, we studied semisimple modules over finite-dimensional algebras. Let us now review the theory of semisimple modules over rings. A (finitely generated)

module  $M$  (over a ring  $R$ ) is **semisimple** if it is isomorphic to a (finite) direct sum of simple modules.

**Definition 15.1.** Let  $R$  be a ring. A left ideal  $L$  is said to be **minimal** if  $L \neq \{0\}$  and there is no left ideal  $L_1$  such that  $\{0\} \subsetneq L_1 \subsetneq L$ .

The ring  $\mathbb{Z}$  contains no minimal left ideals. If  $I$  is a non-zero left ideal of  $\mathbb{Z}$ , then  $I = (n)$  for some  $n > 0$  and  $I = (n) \supsetneq (2n)$ .

**Proposition 15.2.** *Let  $R$  be a left artinian ring. Then every non-zero left ideal contains a minimal left ideal.*

*Proof.* Let  $X$  be the family of non-zero left ideals contained in  $I$ . Then  $X$  is non-empty, as  $I \in X$ . Then  $X$  contains a minimal element by Proposition 10.2.  $\square$

**Definition 15.3.** A ring  $R$  with identity is **semisimple** if it is a direct sum of (finitely many) minimal left ideals.

Why finitely many minimal left ideals? Suppose that  $R = \oplus_{i \in I} L_i$ , where  $\{L_i : i \in I\}$  is a collection of minimal left ideals of  $R$ . Since  $R$  is unitary,  $1 = \sum_{i \in I} e_i$  (finite sum) for some  $e_i \in L_i$ . This means that the set  $J = \{i \in I : e_i \neq 0\}$  is finite. Note that  $R = \oplus_{j \in J} L_j$ , as if  $x \in R$ , then

$$x = x1 = \sum_{j \in J} x e_j \in \bigoplus_{j \in J} L_j.$$

Note that  ${}_R R$  is finitely generated by  $\{1\}$ . Minimal left ideals of  $R$  are exactly the simple submodules of  ${}_R R$ . This means that the ring  $R$  is semisimple if and only if the module  ${}_R R$  is semisimple.

**Proposition 15.4.** *Let  $R$  be a semisimple ring. Then  $R$  is noetherian and artinian.*

*Proof.* Write  $R$  as a direct sum  $R = L_1 \oplus \cdots \oplus L_n$  of minimal left ideals. Since each  $L_j$  is a simple submodule of  ${}_R R$ , it follows that

$$L_1 \oplus \cdots \oplus L_n \supsetneq L_2 \oplus \cdots \oplus L_n \supsetneq \cdots \supsetneq L_n \supsetneq \{0\}$$

is a composition series for  ${}_R R$  with composition factors  $L_1, \dots, L_n$ . Since the module  ${}_R R$  admits a composition series, it is artinian and noetherian by Theorem 10.10. It follows from the definitions that  $R$  is left artinian and left noetherian.  $\square$

**Exercise 15.5.** If  $R$  is a semisimple ring, every  $R$ -module is semisimple.

**Exercise 15.6.** Prove that if  $D$  is a division ring, then  $M_n(D)$  is semisimple.

To see a concrete example, note that  $M_2(\mathbb{R})$  is semisimple, as

$$M_2(\mathbb{R}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right\} = \left\{ \begin{pmatrix} a & 0 \\ b & 0 \end{pmatrix} \right\} \oplus \left\{ \begin{pmatrix} 0 & c \\ 0 & d \end{pmatrix} \right\} \simeq D \oplus D$$

and  $D$  is a minimal left ideal of  $M_2(\mathbb{R})$ .

**Theorem 15.7.** *Let  $R$  be a unitary ring. Then  $R$  is semisimple if and only if  $R$  is left artinian and  $J(R) = \{0\}$ .*

*Proof.* If  $R$  is semisimple, then  $R$  is left artinian by the previous proposition. Moreover, there are finitely many minimal left ideals  $L_1, \dots, L_k$  of  $R$  such that  $R \simeq L_1 \oplus \dots \oplus L_k$ . We claim that for each  $i \in \{1, \dots, k\}$ , the ideal  $M_i = \sum_{j \neq i} L_j$  of  $R$  is maximal. For example, let us prove that  $M_1$  is maximal. If not, there exists a left ideal  $I$  of  $R$  such that  $M_1 \subsetneq I$ . Let  $x \in I \setminus M_1$  and write

$$x = x_1 + x_2 + \dots + x_k$$

for  $x_j \in L_j$ . Since  $x_2 + \dots + x_k \in M_1 \subseteq I$ , it follows that  $x_1 \in I \cap L_1$ , a contradiction.

Conversely, if  $R$  is left artinian and  $J(R) = \{0\}$ , then  $R \simeq M_{n_1}(D_1) \times \dots \times M_{n_k}(D_k)$  for division rings  $D_1, \dots, D_k$ , this is Artin–Wedderburn theorem. Since each  $M_{n_j}(D_j)$  is semisimple, it follows that  $R$  is semisimple.  $\square$

## §16. Hopkins–Levitski theorem

**Theorem 16.1 (Hopkins–Levitski).** *Let  $R$  be a unitary left artinian ring. Then  $R$  is left noetherian.*

*Proof.* Let  $J = J(R)$ . Since  $R$  is left artinian,  $J$  is a nilpotent ideal by Theorem 10.17. Let  $n$  be such that  $J^n = \{0\}$ . Now consider the sequence

$$R \supsetneq J \supsetneq J^2 \supsetneq \dots \supsetneq J^{n-1} \supsetneq J^n = \{0\}.$$

Each  $J^i/J^{i+1}$  is a module over  $R$  annihilated by  $J$ , that is  $J \cdot (J^i/J^{i+1}) = \{0\}$ , as

$$x \cdot (y + J^{i+1}) = xy + J^{i+1} \subseteq JJ^i + J^{i+1} = J^{i+1}$$

if  $x \in J$  and  $y \in J^i$ . Thus each  $J^i/J^{i+1}$  is a module over  $R/J$ . Since  $R/J$  is left artinian and  $J(R/J) = \{0\}$  by Theorem 5.10, it follows that  $R/J$  is semisimple. In particular, since every  $R/J$ -module is semisimple, each  $J^i/J^{i+1}$  is semisimple and hence it is left noetherian.

Now suppose that  $R$  is not left noetherian. Let  $m$  be the largest non-negative integer such that  $J^m$  is not left noetherian. Note that  $0 \leq m < n$ . The sequence

$$0 \longrightarrow J^{m+1} \longrightarrow J^m \longrightarrow J^m/J^{m+1} \longrightarrow 0$$

is exact. Since  $J^{m+1}$  is left noetherian by the definition of  $m$  and  $J^m/J^{m+1}$  is left noetherian, it follows that  $J^m$  is noetherian, a contradiction.  $\square$

**Theorem 16.2 (Connel).** *Let  $K$  be a field of characteristic zero and  $G$  be a group. Then  $K[G]$  is left artinian if and only if  $G$  is finite.*

§16 Hopkins–Levitski theorem

*Proof.* It follows from Theorem 14.7 and Hopkins–Levitzky theorem; see [18, Theorem 1.1 of Chapter 10].  $\square$

## Lecture 9

### §17. Local rings

In this section, we will consider arbitrary rings with one.

**Definition 17.1.** A ring is said to be **local** if it contains only one maximal left ideal.

Division rings are local rings.

**Theorem 17.2.** Let  $R$  be a ring and  $I = R \setminus \mathcal{U}(R)$ . The following statements are equivalent:

- 1)  $R$  is local.
- 2)  $R/J(R)$  is a division ring.
- 3)  $I = J(R)$ .
- 4)  $I$  is an ideal of  $R$ .

*Proof.* We first prove 1)  $\implies$  2). Let  $M$  be the maximal left ideal of  $R$ . Then  $J(R) = M$ . Let  $x \notin M$ . Then  $R = Rx + M$ , so  $1 = rx + m$  for some  $r \in R$  and  $m \in M$ . Thus  $r + M$  is a left inverse of  $x + M$  and hence  $R/M$  is a division ring. In particular,  $r \notin M$ . Since  $R = Rr + M$ , there exists  $y \in R$  such that  $1 = yr$ . Therefore  $y + M$  is a left inverse of  $r + M$ . Thus

$$\begin{aligned} y + M &= (y + M)(1 + M) = (y + M)(r + M)(x + M) \\ &= (yr + M)(x + M) = (1 + M)(x + M) = x + M \end{aligned}$$

and hence  $x + M$  is invertible.

Now we prove 2)  $\implies$  3). Clearly  $J(R) \subseteq I$ . Conversely, let  $x \in I$ . If  $x \notin J(R)$ , then  $x + J(R) \neq 0$ . Since  $R/J(R)$  is a division ring,  $x + J(R) \in \mathcal{U}(R/J(R))$ . In particular,  $1 - rx \in J(R) \subseteq I$  for some  $r \in R$ . Since  $x \in I$ ,  $rx \in I$ . Therefore  $1 = 1 - rx + rx \in I$ , a contradiction.

It is trivial that 3)  $\implies$  4).

Finally, we prove 4)  $\implies$  1). Let  $M$  be a maximal left ideal of  $R$ . Then  $M \subseteq I$ . Since  $M$  is maximal and  $I$  is in particular a left ideal of  $R$ , it follows that  $M = I$ .  $\square$

**Definition 17.3.** An element  $x$  of a ring is said to be **idempotent** if  $x^2 = x$ .

Examples of idempotents are 0 and 1. An idempotent  $x$  is said to be **non-trivial** if  $x \notin \{0, 1\}$ .

**Exercise 17.4.** Let  $p$  be a prime number and  $m > 0$ . Prove that the only idempotents of  $\mathbb{Z}/p^m$  are 0 and 1.

**Exercise 17.5.** How many idempotent does  $\mathbb{Z}/n$  have?

**Exercise 17.6.** Let  $R$  be a ring with one and  $I$  be an ideal of  $R$ . We say that an idempotent  $x \in R/I$  can be lifted if  $x = e + I$  for some idempotent  $e$  of  $R$ . Prove that if every element of  $I$  is nilpotent, then every idempotent of  $R/I$  can be lifted.

The previous exercise shows that if  $R$  is left artinian, every idempotent of  $R/J(R)$  can be lifted to  $R$ .

**Lemma 17.7.** Let  $R$  be a left artinian ring. Then  $J(R)$  is nil.

*Proof.* Let  $x \in J(R)$ . The sequence  $Rx \supseteq Rx^2 \supseteq \cdots$  stabilizes, so  $Rx^n = Rx^{n+1}$  for some  $n$ . In particular, there exists  $r \in R$  such that  $x^n = rx^{n+1}$ . This implies that  $(1 - rx)x^n = 0$ . Since  $x \in J(R)$ , the element  $1 - rx$  is invertible. Hence  $x^n = 0$ .  $\square$

**Theorem 17.8.** Let  $R$  be a left artinian ring. Then  $R$  is local if and only if  $R$  has no non-trivial idempotents.

*Proof.* Let us first prove  $\implies$ . For this implication, we do not need to use that  $R$  is left artinian. Let  $x \in R$  be an idempotent. Then  $x(1 - x) = 0$ . If  $x \in \mathcal{U}(R)$ , then  $x = 1$ . If  $1 - x \in \mathcal{U}(R)$ , then  $x = 0$ . If  $x \notin \mathcal{U}(R)$  and  $1 - x \notin \mathcal{U}(R)$ , then, since  $R \setminus \mathcal{U}(R)$  is an ideal of  $R$ , it follows that  $1 = x + 1 - x \notin \mathcal{U}(R)$ , a contradiction.

Now we prove  $\impliedby$ . By the previous lemma,  $J(R)$  is nil. By the previous exercise, every idempotent of  $R/J(R)$  can be lifted. Thus  $R/J(R)$  has no non-trivial idempotents. On the other hand, by Artin–Wedderburn,

$$R/J(R) \simeq \prod_{i=1}^k M_{n_i}(D_i)$$

for some  $n_1, \dots, n_k \geq 1$  and division rings  $D_1, \dots, D_k$ . Then  $k = n_1 = 1$ , as  $R/J(R)$  has no non-trivial idempotents. Since  $R/J(R)$  is a division ring,  $R$  is local by the previous theorem.  $\square$

**Theorem 17.9.** The center of a local ring is local.

*Proof.* Let  $R$  be a local ring. By Theorem 17.2,  $J(R) = R \setminus \mathcal{U}(R)$ . We need to prove that  $Z(R) \setminus \mathcal{U}(Z(R)) = J(Z(R))$ . We first note that

$$\mathcal{U}(Z(R)) = Z(R) \cap \mathcal{U}(R). \quad (9.1)$$

§18 When is group algebra local?

We claim that  $Z(R) \cap J(R) \subseteq J(Z(R))$ . Let  $x \in Z(R) \cap J(R)$ . Let  $z \in Z(R)$ . Since  $x \in J(R)$ ,  $1 - zx \in \mathcal{U}(R)$ . Moreover,  $1 - zx \in Z(R)$ . Thus

$$1 - zx \in Z(R) \cap \mathcal{U}(R) = \mathcal{U}(Z(R)).$$

Hence  $x \in J(Z(R))$ .

To prove the theorem it is enough to show that  $Z(R) \setminus \mathcal{U}(Z(R)) = J(Z(R))$ . Let us prove the non-trivial inclusion. Let  $x \in Z(R) \setminus \mathcal{U}(Z(R))$ . Then (9.1) implies that  $x \notin \mathcal{U}(R)$ . By Theorem 17.2,  $x \in J(R)$ . Then  $x \in J(R) \cap Z(R) \subseteq J(Z(R))$ .  $\square$

**Exercise 17.10.** Let  $R$  be a local ring. Prove that  $Z(R) = J(R) \subseteq J(Z(R))$ .

**Exercise 17.11.** Prove that a ring is local if and only if it contains only one maximal right ideal.

**Exercise 17.12.** Find a non-local ring with a unique maximal ideal.

**Exercise 17.13.** Let  $R$  be a ring with at least three elements. If  $|\mathcal{U}(R)| = 1$ , then  $R$  is not local.

A ring  $R$  is said to be **Von Neumann regular** if for every non-zero  $r \in R$ ,  $r = rxr$  for some  $x \in R$ .

**Exercise 17.14.** Prove that a ring  $R$  is local if and only if  $R$  is a division ring.

**Exercise 17.15.** Let  $R$  be a ring such that every element of  $R$  is either nilpotent or a unit. Prove that  $R$  is local.

A ring  $R$  is said to be **semilocal** if  $R/J(R)$  is left artinian.

**Exercise 17.16.** Prove the following statements:

- 1) Every local ring is semilocal.
- 2)  $R$  is semilocal if and only if  $R/J(R)$  is semisimple.
- 3) If  $R$  has finitely many maximal ideals, then  $R$  is semilocal.
- 4) If  $R_1, \dots, R_k$  are rings, then  $\bigoplus_{i=1}^k R_i$  is semilocal if and only if each  $R_i$  is semilocal.

**Example 17.17.** Let  $R$  be a ring such that  $R/J(R)$  is commutative. Prove that  $R$  is semilocal if and only if  $R$  has finitely many maximal ideals.

## §18. When is group algebra local?

**Proposition 18.1.** Let  $R$  be a commutative ring with one. Let  $f: G \rightarrow H$  be a group homomorphism with kernel  $K$ . Then

$$\varphi: R[G] \rightarrow R[H], \quad \sum \lambda_i g_i \mapsto \sum \lambda_i f(g_i),$$

is a ring homomorphism with kernel the ideal of  $R[G]$  generated by  $\{k - 1 : k \in K\}$ .

*Proof.* A direct calculation shows that the map  $\varphi$  is a well-defined ring homomorphism. Let  $S = \{k - 1 : k \in K\}$ . Then  $(S) \subseteq \ker \varphi$ .

Let us show that  $\ker \varphi \subseteq (S)$ . Let  $\alpha = \sum r_i g_i \in \ker \varphi$ . Then

$$\varphi(\alpha) = \sum r_i f(g_i) = 0.$$

Let  $\{Kg_{i_1}, \dots, Kg_{i_k}\}$  be the subset of pairwise distinct cosets of  $Kg_1, \dots, Kg_n$ . Write

$$\alpha = \sum \sum s_{ij} k_{ij} g_{i_j}$$

for some  $s_{ij} \in R$  and  $k_{ij} \in K$ . Then

$$0 = \varphi(\alpha) = \sum \sum s_{ij} \varphi(k_{ij} g_{i_j}) = \sum \sum s_{ij} f(g_{i_j}), \quad (9.2)$$

as  $K = \ker f$ . Note that

$$f(g_{i_j}) = f(g_{i_k}) \implies g_{i_j} g_{i_k}^{-1} \in K \implies g_{i_j} K = g_{i_k} K.$$

Thus  $f(g_{i_j}) \neq f(g_{i_k})$  for  $j \neq k$ . Since  $R[H]$  is a free  $R$ -module with basis  $\{h : h \in H\}$ , Equality (9.2) implies that  $\sum_i s_{ij} = 0$  for all  $j$ . Thus

$$\alpha = \sum \sum s_{ij} k_{ij} g_{i_j} = \sum \sum s_{ij} (k_{ij} - 1) g_{i_j} \in (S). \quad \square$$

**Corollary 18.2.** *Let  $R$  be a commutative ring with one. If  $G$  is a group and  $N$  is a normal subgroup of  $G$ , then*

$$R[G/N] \simeq R[G]/I,$$

where  $I$  is the ideal of  $R[G]$  generated by  $\{n - 1 : n \in N\}$ .

*Proof.* Apply the previous proposition to the canonical map  $\pi : G \rightarrow G/N$  to get a ring homomorphism  $\varphi : R[G] \rightarrow R[G/N]$ . The kernel of  $\varphi$  is the ideal  $I$  generated by the set  $\{g - 1 : g \in \ker \pi = N\}$ . Since  $\pi$  is surjective,  $\varphi$  is surjective. Then the claim follows from the first isomorphism theorem.  $\square$

Let  $K$  be a field and  $G$  be a group. We write  $A(K[G])$  to denote the ideal of  $K[G]$  generated by the set  $\{g - 1 : g \in G\}$ . This ideal is known as the **augmentation ideal** of  $K[G]$ .

**Corollary 18.3.** *Let  $K$  be a field. Let  $G$  be a group and  $N$  be a central subgroup of  $G$ . If  $K[N]$  and  $K[G/N]$  are local, then  $K[G]$  is local.*

*Proof.* By Corollary 18.2,  $K[G/N] \simeq K[G]/I$ , where  $I$  is the ideal of  $K[G]$  generated by  $\{n - 1 : n \in N\}$ . Since  $N \subseteq Z(G)$ ,  $I$  is central in  $K[G]$ . Note that

$$I = A(K[N])K[G].$$

Let  $\alpha \in A(K[G])$ . Since  $K[G/N]$  is local,  $A(K[G/N])$  is nil by Theorem 17.2. Since  $K[G]/I \simeq K[G/N]$ , this implies that there exists  $m$  such that  $\alpha^m \in I$ . Since

$K[N]$  is local,  $A(K[N])$  is nil by Theorem 17.2. Moreover,  $K[N]$  is central in  $K[G]$ , because  $N \subseteq Z(G)$ . This implies that  $I = A(K[N])K[G]$  is also nil. In particular,  $\alpha$  is nil. Hence  $K[G]$  is nil and therefore  $K[G]$  is local by Theorem 17.2.  $\square$

**Exercise 18.4.** Let  $R$  be a commutative ring with one and  $G$  be a group. Prove that the map  $R[G] \rightarrow R$ ,  $\sum_{g \in G} r_g g \mapsto \sum_{g \in G} r_g$ , is a surjective ring homomorphism with kernel  $A(R[G])$ .

**Lemma 18.5.** Let  $K$  be a field and  $G$  be a finite group. The following statements are equivalent:

- 1)  $K[G]$  is local.
- 2)  $A(K[G]) \subseteq J(K[G])$ .
- 3)  $A(K[G])$  is nil.
- 4)  $A(K[G]) = J(K[G])$ .

*Proof.* Let us prove that 1)  $\implies$  2). Since  $K[G]$  is local,  $R \setminus \mathcal{U}(K[G]) = J(K[G])$  by Theorem 17.2. Since  $K[G] \setminus \mathcal{U}(K[G])$  contains every proper ideal of  $K[G]$ ,  $A(K[G]) \subseteq J(K[G])$ .

We now prove that 2)  $\implies$  3). Since  $G$  is finite,  $K[G]$  is artinian. By Lemma 17.7,  $J(K[G])$  is nil. Hence  $A(K[G])$  is nil.

We now prove that 3)  $\implies$  4). Since  $J(K[G])$  contains every nil ideal (see Proposition 4.6),  $A(K[G]) \subseteq J(K[G])$ . On the other hand,  $K[G]/A(K[G]) \simeq K$ . Since  $K$  is a field, the correspondence theorem implies that  $A(K[G]) = J(K[G])$ .

Finally, we prove that 4)  $\implies$  1). Since  $A(K[G]) = J(K[G])$ , Exercise 18.4 implies that  $K[G]/J(K[G]) \simeq K$ . Since  $K$  is a field, it is, in particular, a division ring. Thus  $K[G]$  is local by Theorem 17.2.  $\square$

**Exercise 18.6.** Let  $p$  be a prime number,  $K$  be a field of characteristic  $p$  and  $G$  be a cyclic group of order  $p$ . Prove that  $K[G]$  is local.

**Exercise 18.7.** Let  $K$  be a field and  $G$  be a finite group. Then  $K[G]$  is a domain if and only if  $|G| = 1$ .

**Theorem 18.8.** Let  $K$  be a field and  $G$  be a non-trivial finite group. Then  $K[G]$  is local if and only if  $K$  is of characteristic  $p > 0$  and  $G$  is a  $p$ -group.

*Proof.* Let us first prove  $\implies$ . Assume first that  $K$  is a field of characteristic zero. By Maschke's theorem,  $J(K[G]) = \{0\}$ . By Theorem 17.2,  $K[G]$  is a division ring. In particular,  $K[G]$  is a domain, a contradiction (see Exercise 18.7).

Assume now that  $K$  is of characteristic  $p > 0$ . Let  $q$  be a prime divisor of  $|G|$  and  $g \in G$  an element of order  $q$ . Since

$$(1 - g)(1 + \dots + g^{q-1}) = 1 - g^q = 0,$$

$1 - g \notin \mathcal{U}(K[G])$  and  $1 + \dots + g^{q-1} \notin \mathcal{U}(K[G])$ . It follows that  $1 - g^m \notin \mathcal{U}(K[G])$  for all  $m \geq 0$ . By Theorem 17.2,  $K[G] \setminus J(K[G])$  is an ideal. Thus

$$q1_G = 1 + \cdots + g^{q-1} + \sum_{m=1}^{q-1} (1 - g^m) \notin \mathcal{U}(K[G])$$

If  $q \neq 0$  in  $K$ , then  $q1_G \in \mathcal{U}(K[G])$ . Hence  $q = 0$  in  $K$  and therefore  $p$  divides  $q$ . We conclude that  $G$  is a  $p$ -group.

We now prove  $\Leftarrow$ . Let  $G$  be a  $p$ -group and  $K$  be a field of characteristic  $p > 0$ . We proceed by induction on  $|G|$ . If  $|G| = p$ ,  $K[G]$  is a local ring (see Exercise 18.6). If  $|G| > p$ , let  $Z = Z(G)$ . Since  $G$  is a  $p$ -group,  $|Z| \geq p$ . Let  $N$  be a subgroup of  $Z$  of order  $p$ . Then  $|N| < |G|$  and  $|G/N| < |G|$ . By the inductive hypothesis, both  $K[N]$  and  $K[G/N]$  are local. By Corollary 18.3,  $K[G]$  is local too.  $\square$

## §19. Hurewitz' theorem

**Theorem 19.1 (Hurewitz).** *Let  $G$  be a group and  $I$  be the augmentation ideal of  $\mathbb{Z}[G]$ . Then  $G/[G, G] \simeq I/I^2$  as (abelian) groups.*

*Proof.* Let  $\varphi: G \rightarrow I/I^2$ ,  $g \mapsto g - 1_G + I^2$ . Since  $g - 1_G \in I$  for all  $g \in G$ ,  $\varphi$  is well-defined. The map  $\varphi$  is a group homomorphism. Since  $(g - 1_G)(h - 1_G) \in I^2$ ,

$$\begin{aligned} \varphi(gh) &= gh - 1_G + I^2 \\ &= gh - 1_G - (g - 1_G)(h - 1_G) + I^2 + I^2 \\ &= g - 1_G + h - 1_G + I^2 \\ &= \varphi(g) + \varphi(h) \end{aligned}$$

holds for all  $g, h \in G$ .

Since  $[G, G] \subseteq \ker \varphi$ , there exists a group homomorphism

$$\bar{\varphi}: G/[G, G] \rightarrow I/I^2, \quad g[G, G] \mapsto g - 1_G + I^2.$$

We claim that  $\bar{\varphi}$  is an isomorphism. Let us construct the inverse of  $\bar{\varphi}$ . Let

$$\psi: I \rightarrow G/[G, G], \quad \sum_{g \in G} m_g (g - 1_G) \mapsto \left( \prod_{g \in G} g^{m_g} \right) [G, G].$$

Since  $G/[G, G]$  is abelian, the map  $\psi$  is well-defined, that is the order of the factors in  $\prod_{g \in G} g^{m_g}$  does not matter. Note that  $I^2 \subseteq \ker \psi$ , as  $\{(g - 1_G)(h - 1_G) : g, h \in G\}$  generates the additive group  $I^2$  and

$$\begin{aligned} \psi((g - 1_G)(h - 1_G)) &= \psi((gh - 1_G) - (g - 1_G) - (h - 1_G)) \\ &= (ghg^{-1}h^{-1})[G, G] \\ &= [G, G]. \end{aligned}$$

Therefore there exists a group homomorphism

$$\bar{\psi}: I/I^2 \rightarrow G/[G, G], \quad \sum_{g \in G} m_g (g - 1_G) + I^2 \mapsto \left( \prod_{g \in G} g^{m_g} \right) [G, G].$$

A direct calculation shows that  $\bar{\psi}$  is the inverse of  $\bar{\varphi}$ . □

## §20. Andrunakevic–Rjabuhin’s theorem

**Definition 20.1.** A ring  $R$  is **reduced** if has no non-zero nilpotent elements.

Every commutative domain is reduced.

**Example 20.2.** The ring  $\mathbb{Z} \times \mathbb{Z}$  with the usual operations is reduced but not a domain.

**Example 20.3.** The ring  $\mathbb{Z}/6$  is reduced. However,  $\mathbb{Z}/4$  is not reduced.

**Exercise 20.4.** Prove that a ring  $R$  is **reduced** if and only if for all  $r \in R$  such that  $r^2 = 0$  one has  $r = 0$ .

**Exercise 20.5.** Let  $R$  be a commutative ring that is reduced but not a domain. Prove that  $R[X]$  is reduced but not a domain.

The previous exercise and induction shows that if  $R$  is reduced but not a domain, then so is  $R[X_1, \dots, X_n]$ .

**Example 20.6.** Let  $R = \mathbb{Z}/3 \times \mathbb{Z}/3$  with operations  $(a, b) + (c, d) = (a + c, b + d)$  and  $(a, b)(c, d) = (ac, ad + bc)$ . Then  $R$  is a commutative ring with identity  $(1, 0)$ . Since  $(0, 1)$  is a non-zero nilpotent element,  $R$  is not reduced.

**Definition 20.7.** Let  $R$  be a ring and  $I$  be an ideal of  $R$ . Then  $I$  is **reduced** if  $R/I$  is a reduced ring.

Let  $R$  be a ring and  $I$  be a reduced ideal of  $R$ . If  $ab \in I$ , then  $ba \in I$ . In fact, since  $ab \in I$ ,  $(ba)^2 = b(ab)a \in I$ . Since  $R/I$  is reduced,  $ba \in I$ .

**Theorem 20.8 (Andrunakevic–Rjabuhin).** *Let  $R$  be a non-zero ring. If  $R$  is reduced, there exists an ideal  $I$  of  $R$  such that then  $R/I$  has no non-zero zero-divisors.*

Let  $R$  be a ring and  $I$  be an ideal of  $R$ . If  $S$  is a subset of  $R$ , the *left annihilator* of  $S$  modulo  $I$  is the set  $\{r \in R : rS \subseteq I\}$ .

**Lemma 20.9.** *Let  $R$  be a ring and  $I$  be a reduced ideal. If  $S \subseteq R$  is a subset, then the left annihilator of  $S$  modulo  $I$  is a reduced ideal.*

*Proof.* We need to show that  $A = \{r \in R : rS \subseteq I\}$  is a reduced ideal. A straightforward calculation shows that  $A$  is a left ideal. We claim that  $A$  is a right ideal. Let  $r \in R$  and  $a \in A$ . Then  $as \in I$  for all  $s \in S$ . Since  $I$  is reduced,  $sa \in I$  for all  $s \in S$ . Since  $I$  is an ideal of  $R$ ,  $sar \in I$  for all  $s \in S$ . Using again that  $I$  is reduced,  $ars \in I$  for all  $s \in S$ . Thus  $ar \in A$ .

We now claim that  $A$  is reduced. If  $a^2 \in A$ , then  $aas = a^2s \in I$  for all  $s \in S$ . Since  $I$  is reduced,  $asa \in I$  for all  $s \in S$ . Thus  $(as)^2 = (asa)s \in I$  for all  $s \in S$ . Since  $I$  is reduced,  $as \in I$  for all  $s \in S$ . Hence  $a \in A$ .  $\square$

Similarly, if  $S$  is a subset of a ring  $R$ , then the *right annihilator*  $\{r \in R : Sr \subseteq I\}$  of  $S$  modulo  $I$  is a reduced ideal.

*Proof of Theorem 20.8.* Let  $x \in R \setminus \{0\}$ . Let  $X$  be the set of reduced ideals  $I$  such that  $x \notin I$ . Since  $R$  is reduced,  $\{0\}$  is a reduced ideal and hence  $X \neq \emptyset$ . A standard application of Zorn's lemma shows that there exists a maximal element  $M \in X$ .

We claim that  $R/M$  has no non-zero divisors. If not, there exist  $a, b \in R$  such that  $ab \in M$ ,  $a \notin M$  and  $b \notin M$ . Let  $A$  be the left annihilator of  $\{b\}$  modulo  $M$  and  $B$  be the right annihilator of  $\{a\}$  modulo  $M$ . By the previous lemma,  $A$  and  $B$  are reduced ideals of  $R$ . Since  $a \in A$ ,  $M \subseteq A$ . Similarly, since  $b \in B$ ,  $M \subseteq B$ . Moreover,  $AB \subseteq M$ . Since  $x \in A \cap B$ ,  $x^2 \in AB \subseteq M$ . Since  $M$  is reduced,  $x \in M$ , a contradiction.  $\square$

**Exercise 20.10.** Prove that a reduced ring is a subdirect product of rings without non-zero divisors.

**Exercise 20.11.** Is the ring  $\mathbb{C}[\mathbb{Z}/2]$  reduced?

**Open problem 20.1.** Let  $G$  be a torsion-free group. Is  $K[G]$  is reduced?

Problem 20.1 is related to other important open problems about group algebras (e.g. zero-divisors, units, idempotents and semisimplicity of group rings).

**Exercise 20.12.** Prove that idempotents of reduced rings are central.

The previous exercise is used to solve the following problem.

**Exercise 20.13.** Let  $R$  be a ring such that  $x^3 = x$  for all  $x \in R$ . Prove that  $R$  is commutative.

Exercise 20.13 is hard. Even harder is the following exercise:

**Exercise 20.14.** Let  $R$  be a ring such that  $x^4 = x$  for all  $x \in R$ . Prove that  $R$  is commutative.

**Exercise 20.15.** Reduced rings are semiprime.

**Theorem 20.16.** Let  $K$  be a field and  $G$  be a group. If  $K[G]$  is reduced, then every finite subgroup of  $G$  is normal.

§21 Rickart's theorem

*Proof.* Let  $H = \{h_1, \dots, h_n\}$  be a finite normal subgroup of  $G$ . We claim that  $n = |H|$  is invertible in  $K$ . If  $\text{char } K = 0$ , this is clear. If  $\text{char } K = p > 0$  and  $n$  is not invertible in  $K$ , then  $p$  divides  $n = |H|$ . By Cauchy's theorem, there exists an element  $h \in H$  of order  $n$ , that is  $|h| = n$ . Since  $(1 - h)^p = 1 - h^p = 0$  and  $K[G]$  is reduced,  $h = 1$ , a contradiction.

Let  $\alpha = \frac{1}{n} \sum_{i=1}^n h_i \in K[G]$ . Then

$$\alpha^2 = \frac{1}{n^2} \sum_{i=1}^n \sum_{j=1}^n h_i h_j = \frac{1}{n^2} \sum_{i=1}^n n \alpha = \alpha.$$

Thus  $\alpha$  is idempotent. As idempotent element of reduced rings are central (Exercise 20.12),  $g\alpha g^{-1} = \alpha$  for all  $g \in G$ . If  $g \in G$ , then

$$\sum_{i=1}^n g h_i g^{-1} = \sum_{i=1}^n h_i.$$

It follows that  $H$  is normal in  $G$ , as for each  $i \in \{1, \dots, n\}$  there exists  $j \in \{1, \dots, n\}$  such that  $g h_i g^{-1} = h_j \in H$ .  $\square$

**Example 20.17.** If  $K$  is a field, then  $K[\mathbb{S}_3]$  is not reduced. In fact, if

$$\alpha = (12) + (123) - (132) - (13),$$

then  $\alpha^2 = 0$ .

**Exercise 20.18.** Prove that the converse of Theorem 20.16 does not hold.

## §21. Rickart's theorem

We now consider Jacobson's semisimplicity problem.

**Open problem 21.1.** Let  $G$  be a group and  $K$  be a field. When  $J(K[G]) = \{0\}$ ?

As an application of Amitsur's theorem 6.3, we prove that complex group algebras have null Jacobson radical. This is known as Rickart's theorem. The original proof found by Rickart uses complex analysis. Here, however, we present an algebraic proof.

**Theorem 21.2 (Rickart).** *Let  $G$  be a group. Then  $J(\mathbb{C}[G]) = \{0\}$ .*

To prove the theorem, we need a lemma.

**Lemma 21.3.** *Let  $G$  be a group. Then  $J(\mathbb{C}[G])$  is nil.*

*Proof.* We need to show that every element of  $J(\mathbb{C}[G])$  is nilpotent. If  $G$  is countable, then the result follows from Amitsur's theorem 6.3. So assume that  $G$  is not countable. Let  $\alpha \in J(\mathbb{C}[G])$ , say

$$\alpha = \sum_{i=1}^n \lambda_i g_i,$$

where  $\lambda_1, \dots, \lambda_n \in \mathbb{C}$  and  $g_1, \dots, g_n \in G$ . Let  $H = \langle g_1, \dots, g_n \rangle$ . Then  $\alpha \in \mathbb{C}[H]$  and  $H$  is countable. We claim that  $\alpha \in J(\mathbb{C}[H])$ . Decompose  $G$  as a disjoint union

$$G = \bigcup_{\lambda} x_{\lambda} H$$

of cosets of  $H$  in  $G$ . Then  $\mathbb{C}[G] = \bigoplus_{\lambda} x_{\lambda} \mathbb{C}[H]$  and hence  $\mathbb{C}[G] = \mathbb{C}[H] \oplus K$  for some right module  $K$  over  $\mathbb{C}[H]$  (this follows from the fact that one of the cosets is that of  $H$ ). Since  $\alpha \in J(\mathbb{C}[G])$ , for each  $\beta \in \mathbb{C}[H]$  there exists  $\gamma \in \mathbb{C}[G]$  such that  $\gamma(1 - \beta\alpha) = 1$ . Write  $\gamma = \gamma_1 + \kappa$  for  $\gamma_1 \in \mathbb{C}[H]$  and  $\kappa \in K$ . Then

$$1 = \gamma(1 - \beta\alpha) = \gamma_1(1 - \beta\alpha) + \kappa(1 - \beta\alpha)$$

and hence  $\kappa(1 - \beta\alpha) \in K \cap \mathbb{C}[H] = \{0\}$ , as  $\beta \in \mathbb{C}[H]$ . Since  $1 = \gamma_1(1 - \beta\alpha)$ , it follows that  $\alpha \in J(\mathbb{C}[H])$  and the lemma follows from Amitsur's theorem 6.3.  $\square$

We now prove the theorem.

*Proof of Theorem 21.2.* For  $\alpha = \sum_{i=1}^n \lambda_i g_i \in \mathbb{C}[G]$  let

$$\alpha^* = \sum_{i=1}^n \bar{\lambda}_i g_i^{-1}.$$

Then  $\alpha\alpha^* = 0$  if and only if  $\alpha = 0$  and, moreover,  $(\alpha\beta)^* = \beta^*\alpha^*$  for all  $\beta \in \mathbb{C}[G]$ . Assume that  $J(\mathbb{C}[G]) \neq \{0\}$  and let  $\alpha \in J(\mathbb{C}[G]) \setminus \{0\}$ . Then  $\beta = \alpha\alpha^* \in J(\mathbb{C}[G])$ , as  $J(\mathbb{C}[G])$  is an ideal of  $\mathbb{C}[G]$ . Moreover, the previous lemma implies that  $\beta$  is nilpotent. Note that  $\beta \neq 0$ , as  $\alpha \neq 0$ . Now

$$(\beta^m)^* = (\beta^*)^m = \beta^m$$

for all  $m \geq 1$ . If there exists  $k \geq 2$  such that  $\beta^k = 0$  and  $\beta^{k-1} \neq 0$ , then

$$\beta^{k-1} (\beta^{k-1})^* = \beta^{2k-2} = 0$$

and hence  $\beta^{k-1} = 0$ , a contradiction. Thus  $\beta = 0$  and therefore  $\alpha = 0$ .  $\square$

**Exercise 21.4.** If  $G$  is a group, then  $J(\mathbb{R}[G]) = 0$ .

**Definition 21.5.** A ring  $R$  **semiprime** if  $aRa = \{0\}$  implies  $a = 0$ .

**Proposition 21.6.** Let  $R$  be a ring. The following statements are equivalent:

- 1)  $R$  is semiprime.
- 2) If  $I$  is a left ideal such that  $I^2 = \{0\}$ , then  $I = \{0\}$ .
- 3) If  $I$  is an ideal such that  $I^2 = \{0\}$ , then  $I = \{0\}$ .
- 4)  $R$  does not contain non-zero nilpotent ideals.

*Proof.* We first prove that 1)  $\implies$  2). If  $I^2 = \{0\}$  and  $x \in I$ , then  $xRx \subseteq I^2 = \{0\}$  and thus  $x = 0$ . The implications 2)  $\implies$  3) and 4)  $\implies$  3) are both trivial. Let us prove that 3)  $\implies$  4). If  $I$  is a non-zero nilpotent ideal, let  $n \in \mathbb{Z}_{>0}$  be minimal such that  $I^n = \{0\}$ . Since  $(I^{n-1})^2 = \{0\}$ , it follows that  $I^{n-1} = \{0\}$ , a contradiction. Finally, we prove that 3)  $\implies$  1). Let  $a \in R$  be such that  $aRa = \{0\}$ . Then  $I = RaR$  is an ideal of  $R$  such that  $I^2 = \{0\}$ . Thus  $RaR = \{0\}$ . This means that  $Ra$  and  $aR$  are ideals such that  $(Ra)R = R(aR) = \{0\}$  (for example,  $R(aR) \subseteq RaR = \{0\} \subseteq aR$ ). Moreover, since  $(Ra)(Ra) = \{0\}$  and  $(aR)(aR) = \{0\}$ , it follows that  $aR = Ra = \{0\}$ . This implies that  $\mathbb{Z}a$  is an ideal of  $R$ , as  $R(\mathbb{Z}a) \subseteq \mathbb{Z}(Ra) = \{0\}$  and  $(\mathbb{Z}a)R \subseteq aR = \{0\}$ . Now  $(\mathbb{Z}a)(\mathbb{Z}a) \subseteq (\mathbb{Z}a)R = \{0\}$  and hence  $a = 0$ , as  $\mathbb{Z}a = \{0\}$ .  $\square$

Two consequences:

**Exercise 21.7.** A commutative ring is semiprime if and only if it does not contain non-zero nilpotent elements.

**Exercise 21.8.** Let  $D$  be a division ring.

- 1)  $D[X]$  is semiprime and semiprimitive.
- 2)  $D[[X]]$  is semiprime and it is not semiprimitive.

**Corollary 21.9.** The ring  $\mathbb{C}[G]$  is semiprime.

*Proof.* Since  $J(\mathbb{C}[G]) = \{0\}$  by Rickart's theorem and the Jacobson radical contains every nil ideal by Proposition 4.6, it follows that  $\mathbb{C}[G]$  does not contain non-trivial nil ideals. Thus  $\mathbb{C}[G]$  does not contain non-trivial nilpotent ideals and hence  $\mathbb{C}[G]$  is semiprime.  $\square$

**Exercise 21.10.** Prove that  $Z(\mathbb{C}[G])$  is semiprime.

We now characterize when complex group algebras are left artinian. For that purpose, we need a lemma. This is similar to one of the implications proved in Proposition 1.23. However, in the arbitrary setting we are considering, we need to use Zorn's lemma.

**Lemma 21.11.** Let  $M$  be a semisimple module and  $N$  be a submodule. Then  $N$  is a direct summand.

*Sketch of the proof.* Let  $M = \bigoplus_{i \in I} M_i$  be a direct sum of simple modules and let  $i \in I$ . Since  $N \cap M_i$  is a submodule of  $M_i$  and  $M_i$  is simple, it follows that  $N \cap M_i = \{0\}$  or  $N \cap M_i = M_i$ . If  $N \cap M_i = M_i$  for all  $i \in I$ , then  $N = M$  and the lemma is proved. So we may assume that there exists  $i \in I$  such that  $N \cap M_i = \{0\}$ . Let  $X$  be the set of subsets  $J$  of  $I$  such that  $N \cap (\bigoplus_{j \in J} M_j) = \{0\}$ . Our assumptions imply that  $X$  is non-empty. Zorn's lemma implies the existence of a maximal element  $K$ . Let  $N_1 = \bigoplus_{k \in K} M_k$ .

We claim that  $N \oplus N_1 = M$ . If not, there exists  $i \in I$  such that  $M_i \not\subseteq N \oplus N_1$ . The simplicity of  $M_i$  implies that  $M_i \cap (N \oplus N_1) = \{0\}$ , which contradicts the maximality of  $K$ .  $\square$

A direct application of the lemma proves that complex group algebras of infinite groups are never semisimple.

**Proposition 21.12.** *If  $G$  is an infinite group, then  $\mathbb{C}[G]$  is not semisimple.*

*Proof.* Assume that  $R = \mathbb{C}[G]$  is semisimple. Let  $I$  be the augmentation ideal of  $R$ , that is

$$I = \left\{ \alpha = \sum_{g \in G} \lambda_g g \in R : \sum_{g \in G} \lambda_g = 0 \right\}.$$

By the previous lemma, there exists a non-zero ideal  $J$  such that  $R = I \oplus J$ . Since  $R$  is unitary, there exist  $e \in I$  and  $f \in J$  such that  $1 = e + f$ . If  $x \in I$ , then  $x = xe + xf$  and hence  $xf = x - xe \in I \cap J = \{0\}$ . Since  $x = xe$  for all  $x \in I$ , it follows that  $e = e^2$ . Similarly, one proves that  $f^2 = f$ . Moreover,  $ef = 0$ , as  $ef \in I \cap J = \{0\}$ . Since  $I$  is the augmentation ideal of  $R$  and  $If = (Re)f = R(ef) = \{0\}$  (note that  $I = Re$  because  $x = xe$  for all  $x \in I$ ), we conclude that  $(g - 1)f = 0$  for all  $g \in G$ , as  $g - 1 \in I$ . If  $f = \sum_{h \in G} \lambda_h h$  (finite sum), then

$$f = gf = \sum_{h \in G} \lambda_h (gh) = \sum_{h \in G} \lambda_{g^{-1}h} h.$$

Thus  $\lambda_h = \lambda_{g^{-1}h}$  for all  $g, h \in G$ . Since  $G$  is infinite, some  $\lambda_g = 0$  and hence  $f = 0$ . Thus  $e = 1$  and  $I = \mathbb{C}[G]$ , a contradiction.  $\square$

**Theorem 21.13.** *Let  $G$  be a group. Then  $\mathbb{C}[G]$  is left artinian if and only if  $G$  is finite.*

*Proof.* If  $G$  is finite, then  $\mathbb{C}[G]$  is left artinian because  $\dim \mathbb{C}[G] = |G| < \infty$ . So assume that  $G$  is infinite. By Rickart's theorem,  $J(\mathbb{C}[G]) = 0$ . Moreover,  $\mathbb{C}[G]$  is not semisimple by the previous proposition. Thus  $\mathbb{C}[G]$  is not left artinian by Theorem 15.7.  $\square$

## Lecture 10

### §22. Maschke's theorem

We now present another instance of the Jacobson semisimplicity problem. In this case, our result is for finite groups.

**Theorem 22.1 (Maschke).** *Let  $G$  be a finite group. Then  $J(K[G]) = \{0\}$  if and only if the characteristic of  $K$  is zero or does not divide the order of  $G$ .*

*Proof.* Assume that  $G = \{g_1, \dots, g_n\}$ , where  $g_1 = 1$ . Let

$$\rho: K[G] \rightarrow K, \quad \alpha \mapsto \text{trace}(L_\alpha),$$

where  $L_\alpha(\beta) = \alpha\beta$ . Then

$$\rho(g_i) = \begin{cases} n & \text{if } i = 1, \\ 0 & \text{if } 2 \leq i \leq n, \end{cases}$$

as  $L_{g_i}(g_j) = g_i g_j \neq g_j$ , the matrix of  $L_{g_i}$  in the basis  $\{g_1, \dots, g_n\}$  contains zeros in the main diagonal.

Assume that  $J = J(K[G])$  is non-zero and let  $\alpha = \sum_{i=1}^n \lambda_i g_i \in J \setminus \{0\}$ . Without loss of generality we may assume that  $\lambda_1 \neq 0$  (if  $\lambda_1 = 0$  there exists some  $\lambda_i \neq 0$  and we need to take  $g_i^{-1}\alpha \in J$ ). Then

$$\rho(\alpha) = \sum_{i=1}^n \lambda_i \rho(g_i) = n\lambda_1.$$

Since  $G$  is finite,  $K[G]$  is a finite-dimensional algebra and hence  $K[G]$  is left artinian. Since  $J$  is a nilpotent ideal, in particular,  $\alpha$  is a nilpotent element. Then  $L_\alpha$  is nilpotent and hence  $0 = \rho(\alpha) = n\lambda_1$ . This implies that the characteristic of the field  $K$  divides  $n$ .

Conversely, let  $K$  be a field of prime characteristic and that this prime divides  $n$ . Let  $\alpha = \sum_{i=1}^n g_i$ . Since  $\alpha g_j = g_j \alpha = \alpha$  for all  $j \in \{1, \dots, n\}$ , the set  $I = K[G]\alpha$  is an

ideal of  $K[G]$ . Since, moreover,

$$\alpha^2 = \sum_{i=1}^n g_i \alpha = n\alpha = 0$$

in the field  $K$ , it follows that  $I$  is a nilpotent non-zero ideal. Thus  $J(K[G]) \neq \{0\}$ , as Proposition 4.6 yields  $I \subseteq J(K[G])$ .  $\square$

Since the Jacobson radical of a group algebra of a finite group contains every nil left ideal, the following consequence of the theorem follows immediately:

**Corollary 22.2.** *Let  $G$  be a finite group. Then  $K[G]$  does not contain non-zero nil left ideals.*

### §23. Herstein's theorem

Our aim now is to answer the following question: When a group algebra is algebraic? Herstein's theorem provides a solution in the case of fields of characteristic zero. In prime characteristic, the problem is still open.

**Definition 23.1.** A group  $G$  is **locally finite** if every finitely generated subgroup of  $G$  is finite.

If  $G$  is a locally finite group, then every element  $g \in G$  has finite order, as the subgroup  $\langle g \rangle$  is finite because it is finitely generated.

**Example 23.2.** Every finite group is locally finite

**Example 23.3.** The group  $\mathbb{Z}$  is not locally finite because it is torsion-free.

**Example 23.4.** Let  $p$  be a prime number. The **Prüfer's group**

$$\mathbb{Z}(p^\infty) = \{z \in \mathbb{C} : z^{p^n} = 1 \text{ for some } n \in \mathbb{Z}_{>0}\},$$

is locally finite.

**Example 23.5.** Let  $X$  be an infinite set and  $\mathbb{S}_X$  be the set of bijective maps  $X \rightarrow X$  moving only finitely many elements of  $X$ . Then  $\mathbb{S}_X$  is locally finite.

A group  $G$  is a **torsion** group if every element of  $G$  has finite order. Locally finite groups are torsion groups.

**Example 23.6.** Abelian torsion groups are locally finite. Let  $G$  be a locally finite abelian group and  $H$  be a finitely generated subgroup. Since  $G$  is an abelian torsion group, so is  $H$ . Thus  $H$  is finite by the structure theorem of abelian groups.

**Proposition 23.7.** *Let  $G$  be a group and  $N$  be a normal subgroup of  $G$ . If  $N$  and  $G/N$  are locally finite, then  $G$  is locally finite.*

*Proof.* Let  $\pi: G \rightarrow G/N$  be the canonical map and  $\{g_1, \dots, g_n\}$  be a finite subset of  $G$ . Since  $G/N$  is locally finite, the subgroup  $Q$  of  $G/N$  generated by  $\pi(g_1), \dots, \pi(g_n)$  is finite, say

$$Q = \{\pi(g_1), \dots, \pi(g_n), \pi(g_{n+1}), \dots, \pi(g_m)\}$$

for some  $g_{n+1}, \dots, g_m \in G$ .

For each  $i, j \in \{1, \dots, n\}$  there exist  $u_{ij} \in N$  and  $k \in \{1, \dots, m\}$  such that

$$g_i g_j = u_{ij} g_k.$$

Let  $U$  be the subgroup of  $G$  generated by  $\{u_{ij} : 1 \leq i, j \leq n\}$ . Since  $N$  is locally finite,  $U$  is finite. Moreover, since each  $g_i g_j g_l$  can be written as

$$g_i g_j g_l = u_{ij} g_k g_l = u_{ij} u_{kl} g_t = u g_t$$

for some  $u \in U$  and  $t \in \{1, \dots, m\}$ , it follows that the subgroup  $H$  of  $G$  generated by  $\{g_1, \dots, g_n\}$  is finite, as  $|H| \leq m|U|$ .  $\square$

A group  $G$  is **solvable** if there exists a sequence of subgroups

$$\{1\} = G_0 \subsetneq G_1 \subsetneq \dots \subsetneq G_n = G \quad (10.1)$$

where each  $G_i$  is normal in  $G_{i+1}$  and each quotient  $G_i/G_{i-1}$  is abelian.

**Example 23.8.** Abelian groups are solvable.

Subgroups and quotients of solvable groups are solvable.

**Example 23.9.** Groups of order  $< 60$  are solvable.

**Example 23.10.**  $A_5$  and  $S_5$  are not solvable.

A famous theorem of Burnside states that groups of order  $p^a q^b$  for prime numbers  $p$  and  $q$  are solvable. A much harder theorem proved by Feit and Thompson states that groups of odd order are solvable.

**Proposition 23.11.** *If  $G$  is a solvable torsion group, then  $G$  is locally finite.*

*Proof.* We proceed by induction on  $n$ , the length of the sequence (10.1). If  $n = 1$ , then  $G$  is finite because it is abelian and a torsion group. Now assume the result holds for solvable groups of length  $n - 1$  and let  $G$  be a solvable group with a sequence (10.1). Since  $G_{n-1}$  is a solvable torsion group, the inductive hypothesis implies that  $G_{n-1}$  is locally finite. Since  $G/G_{n-1}$  is an abelian torsion group, it is locally finite. The result now follows from Proposition 23.7.  $\square$

We now prove Herstein's theorem.

**Theorem 23.12 (Herstein).** *If  $G$  is a locally finite group, then  $K[G]$  is algebraic. Conversely, if  $K[G]$  is algebraic and  $K$  has characteristic zero, then  $G$  is locally finite.*

*Proof.* Assume that  $G$  is locally finite. Let  $\alpha \in K[G]$ . The subgroup  $H = \langle \text{supp } \alpha \rangle$  is finite, as it is finitely generated. Since  $\alpha \in K[H]$  and  $\dim_K K[H] < \infty$ , the set  $\{1, \alpha, \alpha^2, \dots\}$  is linearly dependent. Thus  $\alpha$  is algebraic over  $K$ .

Let  $\{x_1, \dots, x_m\}$  be a finite subset of  $G$ . Adding inverses if needed, we may assume that  $\{x_1, \dots, x_m\}$  generates the subgroup  $H = \langle x_1, \dots, x_m \rangle$  as a semigroup. Let

$$\alpha = x_1 + \dots + x_m \in K[G].$$

Since  $\alpha$  is algebraic over  $K$ , there exist  $b_0, b_1, \dots, b_{n+1} \in K$  such that

$$b_0 + b_1 \alpha + \dots + b_{n+1} \alpha^{n+1} = 0,$$

where  $b_{n+1} \neq 0$ . Rewrite this as

$$\alpha^{n+1} = a_0 + a_1 \alpha + \dots + a_n \alpha^n$$

for some  $a_0, \dots, a_n \in K$ . Let  $w = x_{i_1} \dots x_{i_{n+1}} \in H$  be a word of length  $n+1$ . Note that

$$\alpha^k = (x_1 + \dots + x_m)^k = \sum x_{i_1} \dots x_{i_k}$$

for all  $k$ . Two words  $x_{i_1} \dots x_{i_k}$  and  $x_{j_1} \dots x_{j_k}$  could represent the same element of the group  $H$ . In this case, the coefficient of  $x_{i_1} \dots x_{i_k} = x_{j_1} \dots x_{j_k}$  in  $\alpha^k$  will be a positive integer  $\geq 2$ .

Since  $K$  is of characteristic zero, it follows that  $w \in \text{supp}(\alpha^{n+1})$ . Since, moreover,  $\alpha^{n+1} = \sum_{j=0}^n a_j \alpha^j$ , it follows that  $w \in \text{supp}(\alpha^j)$  for some  $j \in \{0, \dots, n\}$ . Thus each word in the letters  $x_j$  of length  $n+1$  can be written as a word in the letters  $x_j$  of length  $\leq n$ . Therefore  $H$  is finite and hence  $G$  is locally finite.  $\square$

## §24. Formanek's theorem, I

**Exercise 24.1.** Let  $A$  be an algebraic algebra and  $a \in A$ .

- 1)  $a$  is a left zero divisor if and only if  $a$  is a right zero divisor.
- 2)  $a$  is left invertible if and only if  $a$  is right invertible.
- 3)  $a$  is invertible if and only if  $a$  is not a zero divisor.

**Exercise 24.2.** For  $\alpha = \sum_{g \in G} \alpha_g g \in \mathbb{C}[G]$  let  $|\alpha| = \sum_{g \in G} |\alpha_g| \in \mathbb{R}$ . Prove the following statements:

- 1)  $|\alpha + \beta| \leq |\alpha| + |\beta|$ , and
- 2)  $|\alpha\beta| \leq |\alpha||\beta|$

for all  $\alpha, \beta \in \mathbb{C}[G]$ .

**Theorem 24.3 (Formanek).** Let  $G$  be a group. If every element of  $\mathbb{Q}[G]$  is invertible or a zero divisor, then  $G$  is locally finite.

§24 Formanek's theorem, I

*Proof.* Let  $\{x_1, \dots, x_n\}$  be a finite subset of  $G$ . Adding inverses if needed, we may assume that  $\{x_1, \dots, x_n\}$  generates the subgroup  $H = \langle x_1, \dots, x_n \rangle$  as a semigroup. Let

$$\alpha = \frac{1}{2n}(x_1 + \dots + x_n) \in \mathbb{Q}[G]$$

Note that  $|\alpha| \leq 1/2$ . We claim that  $1 - \alpha \in \mathbb{Q}[G]$  is invertible. If not, then it is a zero divisor. If there exists  $\delta \in \mathbb{Q}[G]$  such that  $\delta(1 - \alpha) = 0$ , then  $\delta = \delta\alpha$ . Since

$$|\delta| = |\delta\alpha| \leq |\delta||\alpha| \leq |\delta|/2,$$

it follows that  $\delta = 0$ . Similarly,  $(1 - \alpha)\delta = 0$  implies  $\delta = 0$ .

Let  $\beta = (1 - \alpha)^{-1} \in \mathbb{Q}[G]$ . For each  $k$  let

$$\gamma_k = (1 + \alpha + \dots + \alpha^k) - \beta.$$

Then

$$\begin{aligned} \gamma_k(1 - \alpha) &= (1 + \alpha + \dots + \alpha^k - \beta)(1 - \alpha) \\ &= (1 + \alpha + \dots + \alpha^k)(1 - \alpha) - \beta(1 - \alpha) = -\alpha^{k+1} \end{aligned}$$

and thus  $\gamma_k = -\alpha^{k+1}\beta$ . Since

$$|\gamma_k| = |-\alpha^{k+1}\beta| \leq |\beta||\alpha^{k+1}| \leq \frac{|\beta|}{2^{k+1}},$$

it follows that  $\lim_{k \rightarrow \infty} |\gamma_k| = 0$ .

We now prove that  $H \subseteq \text{supp } \beta$ . This will finish the proof of the theorem, as  $\text{supp } \beta$  is a finite subset of  $G$  by definition. If  $H \not\subseteq \text{supp } \beta$ , let  $h \in H \setminus \text{supp } \beta$ . Assume that  $h = x_{i_1} \dots x_{i_m}$  is a word in the letters  $x_j$  of length  $m$ . Let  $c_j$  be the coefficient of  $h$  in  $\alpha^j$ . Then  $c_0 + \dots + c_k$  is the coefficient of  $h$  in  $\gamma_k$ , but

$$|\gamma_k| \geq c_0 + c_1 + \dots + c_k \geq c_m > 0$$

for all  $k \geq m$ , as each  $c_j$  is non-negative, a contradiction to  $|\gamma_k| \rightarrow 0$  si  $k \rightarrow \infty$ .  $\square$

## Lecture 11

### §25. Tensor products

The **tensor product** of the vector spaces (over  $K$ )  $U$  and  $V$  is the quotient vector space  $K[U \times V]/T$ , where  $K[U \times V]$  is the vector space with basis

$$\{(u, v) : u \in U, v \in V\}$$

and  $T$  is the subspace generated by elements of the form

$$(\lambda u + \mu u', v) - \lambda(u, v) - \mu(u', v), \quad (u, \lambda v + \mu v') - \lambda(u, v) - \mu(u, v')$$

for  $\lambda, \mu \in K$ ,  $u, u' \in U$  and  $v, v' \in V$ . The tensor product of  $U$  and  $V$  will be denoted by  $U \otimes_K V$  or  $U \otimes V$  when the base field is clear from the context. For  $u \in U$  and  $v \in V$  we write  $u \otimes v$  to denote the coset  $(u, v) + T$ .

**Theorem 25.1.** *Let  $U$  and  $V$  be vector spaces. Then there exists a bilinear map  $U \times V \rightarrow U \otimes V$ ,  $(u, v) \mapsto u \otimes v$ , such that each element of  $U \otimes V$  is a finite sum of the form*

$$\sum_{i=1}^N u_i \otimes v_i$$

*for some  $u_1, \dots, u_N \in U$  and  $v_1, \dots, v_N \in V$ . Moreover, if  $W$  is a vector space and  $\beta: U \times V \rightarrow W$  is a bilinear map, there exists a linear map  $\bar{\beta}: U \otimes V \rightarrow W$  such that  $\bar{\beta}(u \otimes v) = \beta(u, v)$  for all  $u \in U$  and  $v \in V$ .*

*Proof.* By definition, the map

$$U \times V \rightarrow U \otimes V, \quad (u, v) \mapsto u \otimes v,$$

is bilinear. From the definitions, it follows that  $U \otimes V$  is a finite linear combination of elements of the form  $u \otimes v$ , where  $u \in U$  and  $v \in V$ . Since  $\lambda(u \otimes v) = (\lambda u) \otimes v$  for all  $\lambda \in K$ , the first claim follows.

Since the elements of  $U \times V$  form a basis of  $K[U \times V]$ , there exists a linear map

$$\gamma: K[U \times V] \rightarrow W, \quad \gamma(u, v) = \beta(u, v).$$

Since  $\beta$  is bilinear by assumption,  $T \subseteq \ker \gamma$ . It follows that there exists a linear map  $\bar{\beta}: U \otimes V \rightarrow W$  such that

$$\begin{array}{ccc} K[U \times V] & \xrightarrow{\gamma} & W \\ \downarrow & \nearrow & \\ U \otimes V & & \end{array}$$

commutes. In particular,  $\bar{\beta}(u \otimes v) = \beta(u, v)$ .  $\square$

**Exercise 25.2.** Prove that the properties of the previous theorem characterize tensor products up to isomorphism.

Some properties:

**Proposition 25.3.** Let  $\varphi: U \rightarrow U_1$  and  $\psi: V \rightarrow V_1$  be linear maps. There exists a unique linear map  $\varphi \otimes \psi: U \otimes V \rightarrow U_1 \otimes V_1$  such that

$$(\varphi \otimes \psi)(u \otimes v) = \varphi(u) \otimes \psi(v)$$

for all  $u \in U$  and  $v \in V$ .

*Proof.* Since  $U \times V \rightarrow U_1 \otimes V_1$ ,  $(u, v) \mapsto \varphi(u) \otimes \psi(v)$ , is bilinear, there exists a linear map  $U \otimes V \rightarrow U_1 \otimes V_1$ ,  $u \otimes v \mapsto \varphi(u) \otimes \psi(v)$ . Thus

$$\sum u_i \otimes v_i \mapsto \sum \varphi(u_i) \otimes \psi(v_i)$$

is well-defined.  $\square$

**Exercise 25.4.** Prove the following statements:

- 1)  $(\varphi \otimes \psi)(\varphi' \otimes \psi') = (\varphi\varphi') \otimes (\psi\psi')$ .
- 2) If  $\varphi$  and  $\psi$  are isomorphisms, then  $\varphi \otimes \psi$  is an isomorphism.
- 3)  $(\lambda\varphi + \lambda'\varphi') \otimes \psi = \lambda\varphi \otimes \psi + \lambda'\varphi' \otimes \psi$ .
- 4)  $\varphi \otimes (\lambda\psi + \lambda'\psi') = \lambda\varphi \otimes \psi + \lambda'\varphi \otimes \psi'$ .
- 5) If  $U \simeq U_1$  and  $V \simeq V_1$ , then  $U \otimes V \simeq U_1 \otimes V_1$ .

The following proposition is extremely useful:

**Proposition 25.5.** If  $U$  and  $V$  are vector spaces, then  $U \otimes V \simeq V \otimes U$ .

*Proof.* Since  $U \times V \rightarrow V \otimes U$ ,  $(u, v) \mapsto v \otimes u$ , is bilinear, there exists a linear map  $U \otimes V \rightarrow V \otimes U$ ,  $u \otimes v \mapsto v \otimes u$ . Similarly, there exists a linear map  $V \otimes U \rightarrow U \otimes V$ ,  $v \otimes u \mapsto u \otimes v$ . Thus  $U \otimes V \simeq V \otimes U$ .  $\square$

**Exercise 25.6.** Prove that  $(U \otimes V) \otimes W \simeq U \otimes (V \otimes W)$ .

**Exercise 25.7.** Prove that  $U \otimes K \simeq U \simeq K \otimes U$ .

**Proposition 25.8.** Let  $U$  and  $V$  be vector spaces. If  $\{u_1, \dots, u_n\}$  is a linearly independent subset of  $U$  and  $v_1, \dots, v_n \in V$  is such that  $\sum_{i=1}^n u_i \otimes v_i = 0$ , then  $v_i = 0$  for all  $i \in \{1, \dots, n\}$ .

*Proof.* Let  $i \in \{1, \dots, n\}$  and

$$f_i: U \rightarrow K, \quad f_i(u_j) = \delta_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{otherwise.} \end{cases}$$

Since the map  $U \times V \rightarrow V$ ,  $(u, v) \mapsto f_i(u)v$ , is bilinear, there exists a linear map  $\alpha_i: U \otimes V \rightarrow V$  such that  $\alpha_i(u \otimes v) = f_i(u)v$ . Thus

$$v_i = \sum_{j=1}^n \alpha_i(u_j \otimes v_j) = \alpha_i \left( \sum_{j=1}^n u_j \otimes v_j \right) = 0. \quad \square$$

**Exercise 25.9.** Prove that  $u \otimes v = 0$  and  $v \neq 0$  imply  $u = 0$ .

**Theorem 25.10.** Let  $U$  and  $V$  be vector spaces. If  $\{u_i : i \in I\}$  is a basis of  $U$  and  $\{v_j : j \in J\}$  is a basis of  $V$ , then  $\{u_i \otimes v_j : i \in I, j \in J\}$  is a basis of  $U \otimes V$ .

*Proof.* The  $u_i \otimes v_j$  are generators of  $U \otimes V$ , as  $u = \sum_i \lambda_i u_i$  and  $v = \sum_j \mu_j v_j$  imply  $u \otimes v = \sum_{i,j} \lambda_i \mu_j u_i \otimes v_j$ . We now prove that the  $u_i \otimes v_j$  are linearly independent. We need to show that each finite subset of the  $u_i \otimes v_j$  is linearly independent. If  $\sum_k \sum_l \lambda_{kl} u_{i_k} \otimes v_{j_l} = 0$ , then  $0 = \sum_k u_{i_k} \otimes (\sum_l \lambda_{kl} v_{j_l})$ . Since the  $u_{i_k}$  are linearly independent, Proposition 25.8 implies that  $\sum_l \lambda_{kl} v_{j_l} = 0$ . Thus  $\lambda_{kl} = 0$  for all  $k, l$ , as the  $v_{j_l}$  are linearly independent.  $\square$

If  $U$  and  $V$  are finite-dimensional vector spaces, then

$$\dim(U \otimes V) = (\dim U)(\dim V).$$

**Corollary 25.11.** If  $\{u_i : i \in I\}$  is a basis of  $U$ , then every element of  $U \otimes V$  can be written uniquely as a finite sum  $\sum_i u_i \otimes v_i$ .

*Proof.* Every element of  $U \otimes V$  is a finite sum  $\sum_i x_i \otimes y_i$ , where  $x_i \in U$  and  $y_i \in V$ . If  $x_i = \sum_j \lambda_{ij} u_j$ , then

$$\sum_i x_i \otimes y_i = \sum_i \left( \sum_j \lambda_{ij} u_j \right) \otimes y_i = \sum_j u_j \otimes \left( \sum_i \lambda_{ij} y_i \right). \quad \square$$

**Exercise 25.12.** Let  $A$  and  $B$  be algebras. Prove that  $A \otimes B$  is an algebra with

$$(a \otimes b)(x \otimes y) = ax \otimes by.$$

**Exercise 25.13.** Prove the following statements:

- 1)  $A \otimes B \simeq B \otimes A$ .
- 2)  $(A \otimes B) \otimes C \simeq A \otimes (B \otimes C)$ .
- 3)  $A \otimes K \simeq A \simeq K \otimes A$ .
- 4) If  $A \otimes A_1$  and  $B \otimes B_1$ , then  $A \otimes B \simeq A_1 \otimes B_1$ .

Some examples:

**Proposition 25.14.** *If  $G$  and  $H$  are groups, then  $K[G] \otimes K[H] \simeq K[G \times H]$ .*

*Proof.* The set  $\{g \otimes h : g \in G, h \in H\}$  is a basis of  $K[G] \otimes K[H]$  and the elements of  $G \times H$  form a basis of  $K[G \times H]$ . There exists a linear isomorphism

$$K[G] \otimes K[H] \rightarrow K[G \times H], \quad g \otimes h \mapsto (g, h),$$

that is multiplicative. Thus  $K[G] \otimes K[H] \simeq K[G \times H]$  as algebras.  $\square$

**Proposition 25.15.** *If  $A$  is an algebra, then  $A \otimes K[X] \simeq A[X]$ .*

*Proof.* Each element of  $A \otimes K[X]$  can be written uniquely as a finite sum of the form  $\sum a_i \otimes X^i$ . Routine calculations show that  $A \otimes K[X] \mapsto A[X]$ ,  $\sum a_i \otimes X^i \mapsto \sum a_i X^i$ , is a linear algebra isomorphism.  $\square$

**Exercise 25.16.** Prove that if  $A$  is an algebra, then  $A \otimes M_n(K) \simeq M_n(A)$ . In particular,  $M_n(K) \otimes M_m(K) \simeq M_{nm}(K)$ .

Proposition 25.15 and Exercise 25.16 are examples of a procedure known as **scalar extensions**.

**Theorem 25.17.** *Let  $A$  be an algebra over  $K$  and  $E$  be an extension of  $K$  (this just simply means that  $K$  is a subfield of  $E$ ). Then  $A^E = E \otimes_K A$  is an algebra over  $E$  with respect to the scalar multiplication*

$$\lambda(\mu \otimes a) = (\lambda\mu) \otimes a,$$

for all  $\lambda, \mu \in E$  and  $a \in A$ .

*Proof.* Let  $\lambda \in E$ . Since  $E \times A \rightarrow E \otimes_K A$ ,  $(\mu, a) \mapsto (\lambda\mu) \otimes a$ , is  $K$ -bilinear, there exists a linear map  $E \otimes_K A \rightarrow E \otimes_K A$ ,  $\mu \otimes a \mapsto (\lambda\mu) \otimes a$ . The scalar multiplication is then well-defined and

$$\lambda(u + v) = \lambda u + \lambda v$$

for all  $\lambda \in E$  and  $u, v \in E \otimes_K A$ . Moreover,

$$(\lambda + \mu)u = \lambda u + \mu u, \quad (\lambda\mu)u = \lambda(\mu u), \quad \lambda(uv) = (\lambda u)v = u(\lambda v)$$

for all  $u, v \in E \otimes_K A$  and  $\lambda, \mu \in E$ .  $\square$

**Exercise 25.18.** Prove the following statements:

- 1)  $\{1\} \otimes A$  is a subalgebra of  $A^E$  isomorphic to  $A$ .
- 2) If  $\{a_i : i \in I\}$  is a basis of  $A$ , then  $\{1 \otimes a_i : i \in I\}$  is a basis of  $A^E$ .

**Exercise 25.19.** Prove that if  $G$  is a group and  $K$  is a subfield of  $E$ , then

$$E \otimes_K K[G] \simeq E[G].$$

## §26. Formanek's theorem, II

The combination of technique known as extensions of scalars we have seen in the previous section and Formanek's theorem for rational group algebras yield the following general result.

**Theorem 26.1 (Formanek).** *Let  $K$  be a field of characteristic zero and let  $G$  be a group. If every element of  $K[G]$  is invertible or a zero divisor, then  $G$  is locally finite.*

*Proof.* Since  $K$  is of characteristic zero,  $\mathbb{Q} \subseteq K$ . Then  $K[G] \simeq K \otimes_{\mathbb{Q}} \mathbb{Q}[G]$ . Each  $\beta \in K \otimes_{\mathbb{Q}} \mathbb{Q}[G]$  can be written uniquely as

$$\beta = 1 \otimes \beta_0 + \sum k_i \otimes \beta_i,$$

where  $\{1, k_1, k_2, \dots\}$  is a basis of  $K$  as a  $\mathbb{Q}$ -vector space. Let  $\alpha \in \mathbb{Q}[G]$  and let  $\beta \in K[G]$  be such that  $\alpha\beta = 1$ . Since

$$1 \otimes 1 = (1 \otimes \alpha)\beta = 1 \otimes \alpha\beta_0 + \sum k_i \otimes \alpha\beta_i,$$

it follows that  $\alpha\beta_0 = 1$ . Similarly, if  $\alpha\beta = 0$ , then  $\alpha\beta_j = 0$  for all  $j$ . Since each  $\alpha \in \mathbb{Q}[G]$  is invertible or a zero divisor, Formanek's theorems for  $\mathbb{Q}$  applies.  $\square$

## §27. Wedderburn's little theorem

**Definition 27.1.** The  $n$ -th cyclotomic polynomial is defined as the polynomial

$$\Phi_n(X) = \prod (X - \zeta), \quad (11.1)$$

where the product is taken over all  $n$ -th primitive roots of one.

Some examples:

$$\begin{aligned} \Phi_2 &= X - 1, \\ \Phi_3 &= X^2 + X + 1, \\ \Phi_4 &= X^2 + 1, \\ \Phi_5 &= X^4 + X^3 + X^2 + X + 1, \\ \Phi_6 &= X^2 - X + 1, \\ \Phi_7 &= X^6 + X^5 + \dots + X + 1. \end{aligned}$$

**Lemma 27.2.** *If  $n \in \mathbb{Z}_{>0}$ , then*

$$X^n - 1 = \prod_{d|n} \Phi_d(X).$$

*Proof.* Write

$$X^n - 1 = \prod_{j=1}^n (X - e^{2\pi i j/n}) = \prod_{d|n} \prod_{\substack{1 \leq j \leq n \\ \gcd(j,n)=d}} (X - e^{2\pi i j/n}) = \prod_{d|n} \Phi_d(X). \quad \square$$

**Lemma 27.3.** *If  $n \in \mathbb{Z}_{>0}$ , then  $\Phi_n(X) \in \mathbb{Z}[X]$ .*

*Proof.* We proceed by induction on  $n$ . The case  $n = 1$  is trivial, as  $\Phi_1(X) = X - 1$ . Assume that  $\Phi_d(X) \in \mathbb{Z}[X]$  for all  $d < n$ . Then

$$\prod_{d|n, d \neq n} \Phi_d(X) \in \mathbb{Z}[X]$$

is a monic polynomial. Thus  $\Phi_n(X) / \prod_{d|n, d < n} \Phi_d(X) \in \mathbb{Z}[X]$ .  $\square$

**Theorem 27.4 (Wedderburn).** *Every finite division ring is a field.*

*Proof.* Let  $D$  be a finite division ring and  $K = Z(D)$ . Then  $K$  is a finite field, say  $|K| = q$ . We claim that  $|q - \zeta| > q - 1$  for all  $n$ -th root of one  $\zeta \neq 1$ . In fact, write  $\zeta = \cos \theta + i \sin \theta$ . Then  $\cos \theta < 1$  and

$$|q - \zeta|^2 = q^2 - (2 \cos \theta)q + 1 > (q - 1)^2.$$

Note that  $D$  is a  $K$ -vector space. Let  $n = \dim_K D$ . We claim that  $n = 1$ . If  $n > 1$ , the class equation for the group  $D^\times = D \setminus \{0\}$  implies that

$$q^n - 1 = q - 1 + \sum_{j=1}^m \frac{q^n - 1}{q^{d_j} - 1}, \quad (11.2)$$

where  $1 < \frac{q^n - 1}{q^{d_j} - 1} \in \mathbb{Z}$  for all  $j \in \{1, \dots, m\}$ . Since  $d^{d_j} - 1$  divides  $q^n - 1$ , each  $d_j$  divides  $n$ . In particular, (11.1) implies that

$$X^n - 1 = \Phi_n(X)(X^{d_j} - 1)h(X) \quad (11.3)$$

for some  $h(X) \in \mathbb{Z}[X]$ . By evaluating (11.3) in  $X = q$  we obtain that  $\Phi_n(q)$  divides  $q^n - 1$  and that  $\Phi_n(q)$  divides  $\frac{q^n - 1}{q^{d_j} - 1}$ . By (11.2),  $\Phi_n(q)$  divides  $q - 1$ . Thus

$$q - 1 \geq |\Phi_n(q)| = \prod |q - \zeta| > q - 1,$$

as each  $|q - \zeta| > q - 1$ , a contradiction.  $\square$

There are several proofs of Wedderburn's theorem. For example, [23] contains a proof that uses only elementary linear algebra. In [19, Chapter 14] the theorem is proved using group theory.

**Theorem 27.5.** *Let  $D$  be a division ring of characteristic  $p > 0$ . If  $G$  is a subgroup of  $D \setminus \{0\}$ , then  $G$  is cyclic.*

We shall need a lemma. The lemma uses a well-known result from elementary number theory: If  $\varphi$  is the Euler function that counts the positive integers up to a given integer  $n$  that are relatively prime to  $n$ , then

$$\sum_{d|n} \varphi(d) = n.$$

Let us present a quick group-theoretical proof. Let  $G = \langle g \rangle$  be the cyclic group of order  $n$ . Then

$$n = |G| = \sum_{1 \leq d \leq n} |\{g \in G : |g| = d\}| = \sum_{d|n} |\{g \in G : |g| = d\}|$$

by Lagrange's Theorem. Since  $G$  is cyclic, for each  $d | n$ ,  $\langle g^{n/d} \rangle$  is the unique subgroup of  $G$  of order  $d$ . Now the claim follows, as each subgroup of the form  $\langle g^{n/d} \rangle$  has  $\varphi(d)$  generators.

**Lemma 27.6.** *Let  $K$  be a field. Any finite subgroup of  $K \setminus \{0\}$  is cyclic.*

*Proof.* Let  $G$  be a finite subgroup of  $K \setminus \{0\}$  and  $n = |G|$ . For a divisor  $d$  of  $n$ , let  $f(d)$  be the number of elements of  $G$  of order  $d$ . Then

$$\sum_{d|n} f(d) = n. \quad (11.4)$$

We claim that if  $d | n$  is such that  $f(d) \neq 0$ , then  $f(d) = \varphi(d)$ , where  $\varphi$  is the Euler function. In fact, if  $f(d) \neq 0$ , then there exists  $g \in G$  such that  $|g| = d$ . Let  $H = \langle g \rangle$  be the subgroup of  $G$  generated by  $g$ . Every element of  $H$  is a root of the polynomial  $p(X) = X^d - 1 \in K[X]$ . Since  $p(X)$  has at most  $d$  roots,  $H$  is the set of roots of  $p(X)$ . In particular,  $g^m \in H$  and  $|g^m| = d$  if and only if  $\gcd(m, d) = 1$ . Hence  $f(d) = \varphi(d)$ .

Since  $\sum_{d|n} \varphi(d) = n$  and (11.4), it follows that  $f(n) = \varphi(n) \neq 0$ . Hence there exists  $g \in G$  such that  $|g| = n = |G|$  and  $G$  is cyclic.  $\square$

*Proof of Theorem 27.5.* Let  $F = \sum_{g \in G} (\mathbb{Z}/p)g$ . Then  $F$  is a finite subring of  $D$ . Since  $D$  is a domain,  $F$  is a domain. Let  $\alpha \in F \setminus \{0\}$ . Then  $\{\lambda\alpha : \lambda \in F\} = F$ . Since  $\lambda\alpha = 1$  for some  $\lambda \in F$ ,  $F$  is a division ring. By Wedderburn's theorem,  $F$  is a field. Note that  $G \subseteq F$ . Therefore  $G$  is cyclic by the previous lemma.  $\square$

## §28. Zsigmondy's theorem

One of Wedderburn's original proof of Theorem 27.4 uses a result proved by Zsigmondy [25]. Zsigmondy's theorem is quite popular in mathematical contests.

**Theorem 28.1 (Zsigmondy).** *Let  $a > b \geq 1$  be such that  $\gcd(a, b) = 1$  and  $n \geq 2$ . Then there exists a prime divisor of  $a^n - b^n$  that does not divide  $a^k - b^k$  for all  $k \in \{1, \dots, n-1\}$  except when  $n = 2$  and  $a + b$  is a power of two or  $(a, b, n) = (2, 1, 6)$ .*

*Proof.* See for example [24].  $\square$

We now quickly sketch a proof of Wedderburn's theorem 27.4 based on Zsigmondy's theorem.

Let  $D$  be a division ring of dimension  $n$  over  $\mathbb{Z}/p$  for a prime number  $p$ . Assume first that there exists a prime number  $q$  such that  $q \nmid p$  and the order of  $p$  modulo  $q$  is  $n$ . Let  $x \in D \setminus \{0\}$  be an element of order  $q$  and  $F$  be the subring of  $D$  generated by  $x$ . Note that  $F$  is a finite-dimensional  $(\mathbb{Z}/p)$ -vector space. Let  $m = \dim F$ . Since  $x^{p^m-1} = 1$ ,  $q$  divides  $p^m - 1$ . Thus  $m = n$  and hence  $D = F$  is commutative.

Assume now that there is no prime number  $q$  such that  $q \nmid p$  and the order of  $p$  modulo  $q$  is  $n$ . By Zsigmondy's theorem,  $n = 2$  or  $n = 6$  and  $p = 2$ . If  $n = 2$ , then  $D$  is commutative, as it is the subring generated by any element of  $D \setminus \mathbb{Z}/p$ . If  $n = 6$  and  $p = 2$ , then the order of 2 modulo 9 is 6. Since  $D \setminus \{0\}$  contains a subgroup of order 9 and all groups of order 9 are abelian, we can use the previous argument to complete the proof.

## §29. Fermat's last theorem in finite rings

**Theorem 29.1.** *Let  $K$  be a finite field and  $A$  be a finite-dimensional  $K$ -algebra. For  $n \geq 1$ , there exist  $x, y, z \in A \setminus \{0\}$  such that  $x^n + y^n = z^n$  if and only if  $A$  is not a division algebra.*

*Proof.* Assume first that  $A$  is a division algebra. By Wedderburn's theorem,  $A$  is a finite field, say  $|A| = q$ . Then  $x^{q-1} = 1$  for all  $x \in A \setminus \{0\}$ . Hence  $x^n + y^n = z^n$  does not have a solution.

Conversely, assume that  $A$  is not a division algebra. In particular,  $A$  is not a field and  $|A| > 2$ . The equation  $x + y = z$  has a solution in  $A \setminus \{0\}$  (for example,  $x = 1$ ,  $y = z - 1$  and  $z \notin \{0, 1\}$  is a solution). Since  $\dim A < \infty$ , the Jacobson radical  $J(A)$  is nilpotent. There are two cases to consider.

If  $J(A) \neq \{0\}$ , then there exists  $a \in A \setminus \{0\}$  such that  $a^2 = 0$ . Thus  $a^n = 0$  for all  $n \geq 2$ . Hence  $x^n + y^n = z^n$  has a non-trivial solution in  $A \setminus \{0\}$  for all  $n \geq 2$  (for example, take  $x = a$  and  $y = z = 1$ ).

If  $J(A) = \{0\}$ , then  $A$  is semisimple and  $A \simeq \prod_{i=1}^k M_{n_i}(D_i)$  for (finite) division rings  $D_1, \dots, D_k$  and integers  $n_1, \dots, n_k$ . By Wedderburn's theorem, each  $D_i$  is a finite field. We consider two possible cases.

If there exists  $i \in \{1, \dots, k\}$  such that  $n_i > 1$ , then  $M_{n_i}(D_i)$  has non-zero elements such that their squares are zero. Thus there exists  $x \in A \setminus \{0\}$  such that  $x^2 = 0$ . In particular,  $x^n + y^n = z^n$  has a solution.

If  $k \geq 2$ , then  $x = (1, 0, 0, \dots, 0)$ ,  $y = (0, 1, 0, \dots, 0)$  and  $z = (1, 1, 0, \dots, 0)$  is a solution of  $x^n + y^n = z^n$ .  $\square$

## Lecture 12

### §30. Frobenius's theorem

**Theorem 30.1 (Frobenius).** *Every finite-dimensional real division algebra is isomorphic to  $\mathbb{R}$ ,  $\mathbb{C}$  or  $\mathbb{H}$ .*

We present an elementary proof. We shall need some lemmas.

**Lemma 30.2.** *Let  $D$  be a real division algebra such that  $\dim D = n$ . If  $x \in D$ , then there exists  $\lambda \in \mathbb{R}$  such that  $x^2 + \lambda x \in \mathbb{R}$ .*

*Proof.* Since  $\dim D = n$ , the set  $\{1, x, x^2, \dots, x^n\}$  is linearly dependent. So there exists a non-zero polynomial  $f(X) \in \mathbb{R}[X]$  of degree  $\leq n$  such that  $f(x) = 0$ . Without loss of generality, we may assume that the leading coefficient of  $f(X)$  is one. Then we can write  $f(X)$  as a product of polynomials of degree  $\leq 2$ , say

$$f(X) = (X - \alpha_1) \cdots (X - \alpha_r) (X^2 + \lambda_1 X + \mu_1) \cdots (X^2 + \lambda_s X + \mu_s).$$

Since  $D$  is a division algebra and  $f(x) = 0$ , some factor of  $f(X)$  is zero at  $x$ . If  $x - \lambda_j \neq 0$  for all  $j$ , then  $x$  is a root of some  $X^2 + \lambda_k X + \mu_k$ . In any case, there exists  $\lambda \in \mathbb{R}$  such that  $x^2 + \lambda x \in \mathbb{R}$ .  $\square$

**Lemma 30.3.** *Let  $D$  be a real division algebra of dimension  $n$ . Then*

$$V = \{x \in D : x^2 \in \mathbb{R}_{\leq 0}\}$$

*is a subspace of  $D$  such that  $D = \mathbb{R} \oplus V$ .*

*Proof.* If  $x \in D \setminus V$  is such that  $x^2 \in \mathbb{R}$ , then, since  $x^2 > 0$ , it follows that  $x^2 = \alpha^2$  for some  $\alpha \in \mathbb{R}$ . Thus  $x = \pm\alpha \in \mathbb{R}$ , as  $D$  is a division algebra and

$$(x - \alpha)(x + \alpha) = x^2 - \alpha^2 = 0.$$

We claim that  $V$  is a subspace of  $D$ . Note that  $0 \in V$  and that if  $x \in V$ , then  $\lambda x \in V$  for all  $\lambda \in \mathbb{R}$ . Let  $x, y \in V$ . If  $\{x, y\}$  is linearly dependent, then  $x + y \in V$ . If not,

we claim that  $\{1, x, y\}$  is linearly independent. If there exist  $\alpha, \beta, \gamma \in \mathbb{R}$  such that  $\alpha x + \beta y + \gamma = 0$ , then

$$\alpha^2 x^2 = \beta^2 y^2 + 2\beta\gamma y + \gamma^2 = (-\beta y - \gamma)^2.$$

This implies that  $2\beta\gamma y \in \mathbb{R}$  and thus  $\beta\gamma = 0$ . Hence  $\alpha = \beta = \gamma = 0$ . The previous lemma implies that there exist  $\lambda, \mu \in \mathbb{R}$  such that

$$(x+y)^2 + \lambda(x+y) \in \mathbb{R}, \quad (x-y)^2 + \mu(x-y) \in \mathbb{R}.$$

Since

$$(x+y)^2 + (x-y)^2 = 2x^2 + 2y^2 \in \mathbb{R},$$

it follows that  $(\lambda + \mu)x + (\lambda - \mu)y \in \mathbb{R}$ . Since  $\{1, x, y\}$  is linearly independent,  $\lambda = \mu = 0$ . Thus  $(x+y)^2 \in \mathbb{R}$ . If  $x+y \notin V$ , then, the first paragraph of the proof implies that  $x+y \in \mathbb{R}$ , a contradiction.

Clearly,  $\mathbb{R} \cap V = 0$ . If  $x \in D \setminus \mathbb{R}$ , then the previous lemma implies that  $x^2 + \lambda x \in \mathbb{R}$  for some  $\lambda \in \mathbb{R}$ . We claim that  $x + \lambda/2 \in V$ . If not, since

$$(x + \lambda/2)^2 = x^2 + \lambda x + (\lambda/2)^2 \in \mathbb{R},$$

it follows that  $x + \lambda/2 \in \mathbb{R}$  and thus  $x \in \mathbb{R}$ , a contradiction. Hence

$$x = -\lambda/2 + (x + \lambda/2) \in \mathbb{R} \oplus V. \quad \square$$

**Lemma 30.4.** *Let  $D$  be a real algebra of (real) dimension  $n$ . If  $n > 2$ , then there exist  $i, j, k \in D$  such that  $\{1, i, j, k\}$  is linearly independent and*

$$i^2 = j^2 = k^2 = -1, \quad ij = -ji = k, \quad ki = -ik = j, \quad jk = -kj = i. \quad (12.1)$$

*Proof.* Let  $V = \{x \in D : x^2 \in \mathbb{R}, x^2 \leq 0\}$  be the subspace of Lemma 30.3. For  $x, y \in V$  let  $x \circ y = xy + yx = (x+y)^2 - x^2 - y^2 \in \mathbb{R}$ . If  $x \neq 0$ , then  $x \circ x = 2x^2 \neq 0$ . Since  $\dim V = n - 1$ , there exist  $y, z \in V$  such that  $\{y, z\}$  is linearly independent. Let

$$x = z - \frac{z \circ y}{y \circ y} y.$$

Since  $\{y, z\}$  is linearly independent,  $x \neq 0$ . Moreover, since

$$x \circ y = \left( z - \frac{z \circ y}{y \circ y} y \right) \circ y = zy - \frac{z \circ y}{y \circ y} y^2 + yz - \frac{z \circ y}{y \circ y} y^2 = z \circ y - \frac{z \circ y}{y \circ y} y \circ y = 0,$$

it follows that  $xy = -yx$ . Let

$$i = \frac{1}{\sqrt{-x^2}} x, \quad j = \frac{1}{\sqrt{-y^2}} y, \quad k = ij.$$

A direct calculation shows that the formulas of (12.1) hold. For example,

§31 Jacobson's commutativity theorem

$$ji = \frac{1}{\sqrt{-y^2}} \frac{1}{\sqrt{-x^2}} yx = \frac{1}{\sqrt{-x^2}} \frac{1}{\sqrt{-y^2}} (-xy) = -k. \quad \square$$

Now we are finally ready to prove the theorem:

*Proof of 30.1.* Let  $D$  be a real division algebra and let  $n = \dim D$ . If  $n = 1$ , then  $D \simeq \mathbb{R}$ . If  $n = 2$ , the subspace  $V$  of Lemma 30.3 is non-zero and thus there exists  $i \in D$  such that  $i^2 = -1$ . Hence  $D \simeq \mathbb{C}$ . Lemma 30.4 implies that  $n \neq 3$ . If  $n = 4$ , then  $D \simeq \mathbb{H}$ . Suppose that  $n > 4$ . By Lemma 30.4 there exist  $i, j, k \in D$  such that  $\{1, i, j, k\}$  is linearly independent and that the formulas of (12.1) hold. Let

$$V = \{x \in D : x^2 \in \mathbb{R}_{\leq 0}\}.$$

By Lemma 30.3,  $\dim V = n - 1$ . Thus there exists  $x \in V \setminus \langle i, j, k \rangle$ . Let

$$e = x + \frac{i \circ x}{2}i + \frac{j \circ x}{2}j + \frac{k \circ x}{2}k \in V \setminus \{0\}.$$

A direct calculation shows that  $i \circ e = j \circ e = k \circ e = 0$ . Then

$$ek = e(ij) = (ei)j = -(ie)j = -i(ej) = i(je) = (ij)e = ke,$$

a contradiction.  $\square$

### §31. Jacobson's commutativity theorem

**Exercise 31.1.** A ring  $R$  is **boolean** if  $x^2 = x$  for all  $x \in R$ . Prove that boolean rings are commutative.

To prove this fact, note that  $1 = (-1)^2 = -1$ . This means that  $R$  has characteristic two. Let  $x, y \in R$ . Since  $x + y = (x + y)^2 = x^2 + xy + yx + y^2$ , it follows that  $0 = xy + yx$  and hence  $xy = yx$ .

**Proposition 31.2.** Let  $R$  be a finite ring such that for each  $x \in R$  there exists  $n(x) \geq 2$  such that  $x^{n(x)} = x$ . Then  $R$  is commutative.

*Proof.* Since  $R$  is finite,  $R$  is artinian and hence  $J(R)$  is nil. Since  $R$  is reduced,  $J(R) = \{0\}$ . By the Artin–Wedderburn theorem,  $R \simeq \prod_{i=1}^k M_{n_i}(D_i)$  for some division rings  $D_1, \dots, D_k$ . Since  $R$  is finite, each  $D_i$  is finite. By Wedderburn's theorem, every  $D_i$  is a field. Again, since  $R$  is reduced,  $n_i = 1$  for all  $i$ . Therefore  $R$  is commutative, as it is direct product of finitely many fields.  $\square$

In this lecture, we will prove extend the result of Proposition 31.2 to arbitrary (i.e. non-finite) rings.

**Theorem 31.3 (Jacobson).** Let  $R$  be a ring such that for each  $x \in R$  there exists  $n(x) \geq 2$  such that  $x^{n(x)} = x$ . Then  $R$  is commutative.

We shall need the following lemma.

**Lemma 31.4.** *Let  $K$  be a finite field of characteristic  $p > 0$ . There exists  $n \in \mathbb{Z}_{>0}$  such that  $|K| = p^n$  and  $x^{p^n} = x$  for all  $x \in K$ . Moreover, if  $K \setminus \{0\} = \{x_1, \dots, x_{p^n-1}\}$ , then  $X^{p^n} - X = (X - x_1) \cdots (X - x_{p^n-1})X$ .*

*Proof.* The field  $K$  is a  $(\mathbb{Z}/p)$ -vector space. If  $\dim_{\mathbb{Z}/p} K = n$ , then  $|K| = p^n$ . In particular,  $K \setminus \{0\}$  is an abelian group of order  $p^n - 1$  and hence, by Lagrange's theorem,  $x^{p^n-1} = 1$  for all  $x \in K \setminus \{0\}$ . Thus  $x^{p^n} = x$  for all  $x \in K$  and hence every  $x \in K$  is a root of the polynomial  $X^{p^n} - X$  of degree  $p^n$ .  $\square$

Let  $R$  be a ring. For each  $r \in R$  the map  $\text{ad } r: R \rightarrow R, x \mapsto rx - xr$ , is a derivation. This means that  $\text{ad}(xy) = (\text{ad } x)y + x(\text{ad } y)$  for all  $x, y \in R$ . By induction one proves that

$$(\text{ad } r)^n(x) = \sum_{k=0}^n (-1)^k \binom{n}{k} r^{n-k} x r^k \quad (12.2)$$

for all  $x \in R$  and  $n \in \mathbb{Z}_{>0}$ . If  $p$  is a prime number,  $p$  divides  $\binom{p}{k}$  for all  $k \in \{1, \dots, p-1\}$ . This fact is needed to solve the following exercise:

**Exercise 31.5.** Let  $p$  be a prime number and  $R$  be a ring of characteristic  $p$ . Prove that  $(\text{ad } r)^{p^n} = \text{ad } r^{p^n}$ .

Now we are ready to prove Jacobson's commutativity theorem.

*Proof of Theorem 31.3.* We divide the proof in several steps and claims. We may assume that  $R$  is non-zero.

*Claim.*  $J(R) = \{0\}$ .

Let  $x \in J(R)$  and  $n = n(x)$ . Since  $-x^{n-1} \in J(R)$ , there exists  $y \in R$  such that  $-x^{n-1} \circ y = -x^{n-1} + y - x^{n-1}y = 0$ . Thus

$$-x^{n-1} + y = x^{n-1}y \implies -x + xy = x(-x^{n-1} + y) = x^n y = xy.$$

This implies that  $x = 0$ .

*Claim.* Without loss of generality we may assume that  $R$  is primitive.

Let  $\{P_i : i \in I\}$  be the collection of primitive ideals of  $R$ . The map  $R \rightarrow \prod_{i \in I} R/P_i, r \mapsto (r + P_i)_{i \in I}$ , is an injective homomorphism, since its kernel is

$$\bigcap_{i \in I} P_i = J(R) = \{0\}.$$

Note that  $R$  is commutative if and only if each  $R/P_i$  is commutative. Moreover, each  $R/P_i$  satisfies the assumption, that is  $(x + P_i)^{n(x)} = x^{n(x)} + P_i = x + P_i$ , and is a primitive ring.

*Claim.*  $R$  is a division ring.

By Jacobson's density theorem, there exists a division ring  $D$  and a  $D$ -vector space  $V$  such that  $R$  is dense in  $V$ . We claim that  $\dim_D V = 1$ . If  $\dim_D V \geq 2$ , let  $\{v_1, v_2\} \subseteq V$  be a linearly independent set. Then there exists  $f \in R$  such that  $f(v_1) = v_2$  and  $f(v_2) = 0$ . This implies that  $f^k(v_1) = 0$  for all  $k \geq 2$  and  $f(v_1) \neq 0$ . This contradicts the fact that  $f^n = f$  for  $n = n(f)$ . Thus  $R \simeq D^{\text{op}}$ , a division ring.

*Claim.*  $R$  has positive characteristic.

Since  $R$  is a division ring,  $2 = 1 + 1 \in R$ . There exists  $n \geq 2$  such that  $2^n = 2$ . In particular,  $2(2^{n-1} - 1) = 0$ . This implies the claim.

*Claim.* Every non-zero subring of  $R$  is a division ring.

Let  $S \subseteq R$  is a non-zero subring of  $R$ . If  $x \in S \setminus \{0\}$ , then  $x^{n(x)} = x$ . In particular,  $x^{-1} = x^{n(x)-2} \in S$ .

*Claim.*  $R$  is commutative.

Let us assume that  $R$  is not commutative. Let  $x \in R \setminus Z(R)$ . Since  $R$  has positive characteristic, there exists  $m > 0$  such that  $mx = 0$ . Moreover, since  $R$  is a division ring and  $x^{n(x)} = x$ , it follows that  $x^{n(x)-1} = 1$ . These facts imply that the subring  $K$  of  $R$  generated by  $x$  is finite. By Wedderburn's theorem,  $K$  is a finite field. Thus  $|K| = p^k$  for some prime number  $p$  and some  $k > 0$  and

$$x^{p^k} = x.$$

Note that  $R$  is a  $K$ -vector space and  $\delta = \text{ad } x: R \rightarrow R, y \mapsto xy - yx$ , is a  $K$ -linear map. Moreover, by the exercise,

$$\delta^{p^k} = (\text{ad } x)^{p^k} = \text{ad } (x^{p^k}) = \text{ad } x = \delta$$

and

$$\delta(\delta - x_1 \text{id}) \cdots (\delta - x_{p^k-1} \text{id}) = 0 \quad (12.3)$$

if  $K = \{0, x_1, \dots, x_{p^k-1}\}$ . Since  $x$  is not central,  $\delta$  is non-zero. So there exists  $y \in R$  such that  $\delta(y) \neq 0$ . Evaluating (12.3) in  $y$  and using that  $R$  is a division ring we obtain that

$$x_i y = \delta(y) = xy - yx$$

for some  $i$ . Let  $R_0$  be the subring of  $R$  generated by  $x$  and  $y$ . Since  $xy - yx = \delta(y) \neq 0$ , the ring  $R_0$  is a non-commutative division ring. Note that  $yx = (x - x_i)y \in Ky$ , as  $x \in K$  and  $x_i \in K$ . By induction one proves that  $yx^j \subseteq Ky$  for all  $j \geq 1$  and hence  $y^i K \subseteq Ky^i$  for all  $i \geq 1$ . This implies that

$$K + Ky + \cdots + Ky^{n(y)-2} \subseteq R$$

is a subring. It follows that  $K + Ky + \cdots + Ky^{n(y)-2} = R_0$ , as it is a subring of  $R$  included in  $R_0$  that contains  $x$  and  $y$ . Since  $R_0$  is a finite division ring, it is a field by Wedderburn's theorem, a contradiction since it is non-commutative.  $\square$

There are elementary proofs of Jacobson's commutativity theorem. See for example [16].

### §32. Skolem–Noether theorem

**Definition 32.1.** Let  $K$  be a field. An algebra  $A$  (over  $K$ ) is **central** if  $Z(A) = K$ .

If  $K$  is a field, then  $M_n(K)$  is a central algebra.

**Proposition 32.2.** Let  $A$  be a unitary algebra and  $n \geq 1$ . Then  $A$  is central if and only if  $M_n(A)$  is central.

*Proof.* If  $M_n(A)$  is central and  $z \in Z(A)$ , then  $zI \in Z(M_n(A)) = KI$ . Thus  $z \in K$ . Conversely, if  $X \in Z(M_n(A))$ , then, since  $XE_{kl} = E_{kl}X$  for all  $k \neq l$ ,  $X = aI$  for some  $a \in A$ . Moreover,  $XaE_{11} = aE_{11}X$ . Hence  $a \in Z(A) = K1$ .  $\square$

**Example 32.3.**  $\mathbb{H}$  is a real central algebra.

**Example 32.4.**  $\mathbb{C}$  is a complex central algebra but it is not a real central algebra.

Frobenius' theorem 30.1 translates into the following statement: Every finite-dimensional real central division algebra is isomorphic to  $\mathbb{R}$  or  $\mathbb{H}$ .

**Proposition 32.5.** Every simple unitary ring is an algebra over its center.

*Proof.* Let  $R$  be a simple unitary ring. It is enough to show that  $Z(R)$  is a field. If  $z \in Z(R) \setminus \{0\}$  then  $zR$  is a non-zero ideal of  $R$ . Since  $R$  is simple,  $zR = R$ . Thus  $z$  is invertible.  $\square$

For an algebra  $A$ , let  $L: A \rightarrow \text{End}_K(A)$ ,  $a \mapsto L_a$ , and  $R: A \rightarrow \text{End}_K(A)$ ,  $a \mapsto R_a$ , be given by  $L_a(x) = ax$  and  $R_a(x) = xa$ . Then both  $L$  and  $R$  are linear maps such that

$$L_{ab} = L_a L_b, \quad R_{ab} = R_b R_a, \quad L_a R_b = R_b L_a$$

for all  $a, b \in A$ .

**Definition 32.6.** Let  $A$  be an algebra. The **algebra of multipliers** of  $A$  is

$$M(A) = \left\{ \sum_{j=1}^n L_{a_j} R_{b_j} : n \in \mathbb{Z}_{\geq 0}, a_1, \dots, a_n, b_1, \dots, b_n \in A \right\}.$$

It is an exercise to show that  $M(A)$  is a subalgebra of  $\text{End}_K(A)$ . Moreover, if  $A$  is unitary, then  $M(A)$  is generated by the  $L_a$  and the  $R_b$  for  $a, b \in A$ .

**Lemma 32.7.** *Let  $A$  be an algebra and  $f \in M(A)$ . Then there exists  $n \geq 0$  and  $a_1, \dots, a_n \in A$  and  $b_1, \dots, b_n \in A$  such that*

$$f = \sum_{i=1}^n L_{a_i} R_{b_i}$$

*and  $\{b_1, \dots, b_n\}$  is linearly independent.*

*Proof.* Write  $f = \sum_{i=1}^n L_{a_i} R_{b_i}$  with  $n$  be minimal. If  $b_n = \sum_{j=1}^{n-1} \lambda_j b_j$ , then

$$f = \sum_{i=1}^{n-1} L_{a_i + \lambda_i a_n} R_{b_i},$$

a contradiction. □

**Lemma 32.8.** *Let  $A$  be a central simple algebra. If  $\sum_{i=1}^n L_{a_i} R_{b_i} = 0$  and  $\{b_1, \dots, b_n\}$  (resp.  $\{a_1, \dots, a_n\}$ ) is linearly independent, then  $a_i = 0$  (resp.  $b_i = 0$ ) for all  $i$ .*

*Proof.* The result holds for  $n = 1$ . We want to prove that if  $a_1 x b_1 = 0$  for all  $x \in A$  and  $b_1 \neq 0$ , then  $a_1 = 0$ . Assume that  $a_1 \neq 0$ . The ideal of  $A$  generated by  $a_1$  is non-zero, and hence it is equal to  $A$ . Thus there exist  $u_1, \dots, u_m, v_1, \dots, v_m \in A$  such that  $1 = \sum_{j=1}^m u_j a_1 v_j$ . Write

$$0 = \sum_{j=1}^m L_{u_j} (L_{a_1} R_{b_1}) L_{v_j} = \sum_{j=1}^m L_{u_j a_1 v_j} R_{b_1} = R_{b_1}.$$

Hence  $b_1 = 0$ .

Assume that the lemma is not true and let  $n > 1$  be the smallest positive integer where the lemma is false. Assume that  $a_n \neq 0$ . Since  $A$  is simple, the ideal generated by  $a_n$  is  $A$ . Then there exist  $u_1, \dots, u_m, v_1, \dots, v_m \in A$  such that  $1 = \sum_{j=1}^m u_j a_1 v_j$  and

$$0 = \sum_{j=1}^m L_{u_j} \left( \sum_{i=1}^n L_{a_i} R_{b_i} \right) L_{v_j} = \sum_{i=1}^n \sum_{j=1}^m L_{u_j a_i v_j} R_{b_i} = \sum_{i=1}^n L_{c_i} R_{b_i},$$

where  $c_i = \sum_{j=1}^m u_j a_i v_j$  and  $c_n = 1$ . Since

$$0 = L_x \left( \sum_{i=1}^n L_{c_i} R_{b_i} \right) - \left( \sum_{i=1}^n L_{c_i} R_{b_i} \right) L_x = \sum_{i=1}^{n-1} L_{x c_i - c_i x} R_{b_i}$$

for all  $x \in A$ , it follows that  $x c_i - c_i x = 0$  for all  $x \in A$ . Since  $A$  is central,  $c_i \in k$  for all  $i \in \{1, \dots, n-1\}$ . Evaluate  $0 = \sum_{i=1}^n L_{c_i} R_{b_i}$  in  $1_A$  we obtain that  $0 = c_1 b_1 + \dots + c_n b_n$ , a contradiction since  $\{b_1, \dots, b_n\}$  is linearly independent. □

**Lemma 32.9.** *If  $A$  is a finite-dimensional central simple algebra, then*

$$M(A) = \text{End}_K(A).$$

*Proof.* Let  $\{a_1, \dots, a_n\}$  be a basis of  $A$ . We claim that  $\{L_{a_i}R_{a_j} : 1 \leq i, j \leq n\}$  is linearly independent. If

$$\sum_{i,j=1}^n \lambda_{ij} L_{a_i} R_{a_j} = 0,$$

then  $\sum_{i=1}^n L_{a_i} R_{c_i} = 0$ , where  $c_i = \sum_{j=1}^n \lambda_{ij} R_{a_j}$ . Since the  $a_i$ 's are linearly independent, Lemma 32.8 implies that  $c_i = 0$  for all  $i \in \{1, \dots, n\}$ , a contradiction since the  $a_j$ 's are linearly independent. Hence  $\dim_k M(A) \geq n^2 = \dim \text{End}_K(A)$ .  $\square$

**Definition 32.10.** Let  $R$  be a unitary ring. An automorphism  $f \in \text{Aut}(R)$  is **inner** if there exists an invertible  $r \in R$  such that  $f(x) = r x r^{-1}$  for all  $x \in R$ .

For example,  $\mathbb{C} \rightarrow \mathbb{C}, z \mapsto \bar{z}$ , is not inner.

**Example 32.11.** Let  $\lambda \in k \setminus \{0\}$  and  $R = k[X]$ . Then

$$k[X] \rightarrow k[X], \quad f(X) \mapsto f(X + \lambda),$$

is not inner.

**Example 32.12.** Let  $R$  be a ring. Then  $R \times R \rightarrow R \times R, (x, y) \mapsto (y, x)$ , is not inner.

**Theorem 32.13 (Skolem–Noether).** *If  $A$  is a finite-dimensional central simple algebra, every automorphism of  $A$  is inner.*

*Proof.* Let  $f \in \text{Aut}(A)$ . By Lemma 32.9,  $f = \sum_{i=1}^n L_{a_i} R_{b_i}$ . Without loss of generality, we may assume that  $a_1 \neq 0$  and that  $\{b_1, \dots, b_n\}$  is linearly independent. Since  $f$  is a homomorphism,  $L_{f(x)}f = fL_x$  for all  $x \in A$ . Then

$$0 = \sum_{i=1}^n L_{f(x)a_i - a_i x} R_{b_i}.$$

By Lemma 32.8,  $f(x)a_1 - a_1 x = 0$  for all  $x \in A$ . We claim that  $a_1$  is invertible. Since  $a_1 \neq 0$  and  $A$  is simple, the ideal of  $A$  generated by  $a_1$  is  $A$ . Write  $1 = \sum_{j=1}^m u_j a_1 v_j$ . Thus  $a_1$  is invertible, as

$$\left( \sum_{j=1}^m u_j f(v_j) \right) a_1 = a_1 \left( \sum_{j=1}^m f^{-1}(u_j) v_j \right) = 1. \quad \square$$

## Some topics for final projects

We collect here some topics for final presentations. Some topics can also be used as bachelor or master theses.

### *Rickart's theorem*

In Lecture 9 we presented an algebraic proof of Rickart's theorem. The original proof uses analysis; see [14, (6.4) of Chapter II].

### *Connel's theorem*

In Lecture 11 we presented the statement of Connel's theorem, which characterizes prime group rings over fields of characteristic zero (see Theorem 14.7); the proof of this result appears for example in [18, Theorem 2.10 of Chapter 4]. As a corollary, one obtains that, if  $K$  is a field of characteristic zero, then the group ring  $K[G]$  is left artinian if and only if the group  $G$  is finite; see [18, Theorem 1.1 of Chapter 10] for a proof.

### *Kolchin's theorem*

Let  $U_n(\mathbb{C})$  be the subgroup of  $\mathbf{GL}_n(\mathbb{C})$  of matrices  $(u_{ij})$  such that

$$u_{ij} = \begin{cases} 1 & \text{if } i = j, \\ 0 & \text{if } i > j. \end{cases}$$

A matrix  $a \in \mathbf{GL}_n(\mathbb{C})$  is said to be **unipotent** if its characteristic polynomial is of the form  $(X - 1)^n$ . A subgroup  $G$  of  $\mathbf{GL}_n(\mathbb{C})$  is said to be **unipotent** if each  $g \in G$  is unipotent.

An important theorem of Kolchin states that every unipotent subgroup of  $\mathbf{GL}_n(\mathbb{C})$  is conjugate of some subgroup of  $U_n(\mathbb{C})$ . The theorem and its proof appear, for example, in the VUB course Representation theory of algebras.

### ***Dedekind-finite rings***

The idea is to develop basic aspects of Dedekind-finite rings. A standard reference is Lam's book [15].

### ***Skolem–Noether theorem***

Any automorphism of the full  $n \times n$  matrix algebra is conjugation by some invertible  $n \times n$  matrix. This is an elementary instance of the celebrated Skolem–Noether theorem. We refer to [2, Chapter 4] for the theorem and its proof (in a more general context).

### ***Double centralizer theorem***

Let  $R$  be a ring. The centralizer of a subring  $S$  of  $R$  is

$$C_R(S) = \{r \in R : rs = sr \text{ for all } s \in S\}.$$

Clearly,  $C_R(C_R(S)) \supseteq S$ , but equality does not always hold. The double centralizer theorems give conditions under which one can conclude that equality occurs; see [2, Chapter 4].

### ***Amitsur–Levitzki theorem***

The theorem states that if  $A$  is a commutative algebra, then the matrix algebra  $M_n(K)$  satisfies the identity

$$s_{2n}(a_1, \dots, a_{2n}) = 0,$$

where

$$s_n(X_1, \dots, X_n) = \sum_{\sigma \in \mathbb{S}_n} \text{sign}(\sigma) X_{\sigma(1)} \cdots X_{\sigma(n)}.$$

See [2, Theorem 6.39] for the beautiful proof found by Rosset.

### ***Non-commutative Hilbert's basis theorem***

There exists a non-commutative version of the celebrated Hilbert's basis theorem. It is based on the theory of Ore's extensions (also known as *skew polynomial rings*). The theorem appears in [11, I.8.3]; see [11, I.7] for the basic theory of Ore's extensions.

### ***Bi-ordered or left-ordered groups***

Basic notions about ordered groups appear in the book of Passman [18], where the motivation is based on algebraic properties of group algebras.

### ***Golod-Shafarevich theorem***

This is an important theorem of non-commutative algebra with several interesting applications, for example, in group theory. A quick proof (and some applications) can be found in the book [8] of Herstein.

### ***The Brauer group***

The Brauer group is a helpful tool to classify division algebras over fields. It can also be defined in terms of Galois cohomology. See [3] for the definition and some properties.

### ***The Weyl algebra***

The Weyl algebra is the quotient of the free algebra on two generators  $X$  and  $Y$  by the ideal generated by the element  $YX - XY - 1$ . The Weyl algebra is a simple ring that is not a matrix ring over a division ring. It is also a non-commutative domain and an Ore extension. See [14] for more information. In 1968, Dixmier conjectured that any endomorphism of a Weyl algebra is an automorphism; the conjecture is still open.

### ***Gardam's theorem***

Let  $K$  be a field and  $G$  be a torsion-free group. What do the units of  $K[G]$  look like? The conjecture is that units of  $K[G]$  are of the form  $\lambda g$  for some  $0 \neq \lambda \in K$  and  $g \in G$ . Recently, Gardam [4] found a counterexample in the case that  $K$  is the field of two elements. The problem is still open for fields of characteristic zero.
